"Cut out the resistor and use an ATU."

Sounds good. It may be even easier to leave the terminating resistor in place and bypass it with a piece of copper wire secured with copper split-bolt (Burndy) connectors.

I't's not the oil it's the load resistor.
You can expect some change in SWR as you increase in frequency but it should be small. If your expoeriencing a large change then I suspect your load resistor has some inductance associated with it.

Does anyone have any experience with the OA-432? I was thinking of picking up a dualband 2m/70cm yagi for SSB work (it would replace my 2m quad currently up for SSB on 2m), but now I am thinking of just getting the Par Antenna OA-432. I probably wouldn't be using 432 SSB very much, mainly during contests. Opinions are greatly appretiated. Thanks!

>
> Thanx!

You mean two inverted vees parallel? The lengths will depend on the
frequency and surroundings. You just trim the wires for best match at
the freq you want.
The angles of the wires do not really matter much. There is only one
rule I try to follow, and thats to not have the legs of a dipole or
inv vee at less than 90 degrees apart. But even if you do that it will
work. Just not quite as well. If you are running dipoles in parallel,
I'd try to keep them as far apart as possible. Right angles are best
for two bands. MK

Duane;

Use Formula of 468/f(MHz) to determine center frequency length. Using
two "vees" at right angle should cause minimal effect and require
little, if any, trimming.

Good luck,
Jim, K4SQR

1667. Re: Radioshack DiscOne Base Antenna vs 6 meter dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-24 12:07:52 UTC
From: discone <nospam@aol.com>
Message-ID: <f05tjucahh63fdie252s7m8oi99gojb151@4ax.com>
Source record: 138109

The RS discone is only going to cover about 1 MHz bandwidth on 6
meters because on 6, because it is using the base-loaded vertical
radiator part of the antenna. Your signal will be omni-directional
and vertically polarized.

As far as 6 meters is concerned, you would be just as well off with a
vertical dipole, vertical coaxial, or even a base loaded 5/8 wave 2
meter antenna..... which would be a 1/4 on 6m.

A discone will cover a 10 : 1 frequency range. The lower cutoff
frequency is determined by the length of the "skirt". The length of
the skirt is 1/4 wavelength at the lowest frequency. The diameter of
the disk is 70% of that length. This RS model is probably designed
to cover 130 - 1300 MHz. The reported coverage outside this range is
due to the base-loaded vertical section.

hope this helps.............

Par makes a good product but you'd be just as well off putting up a
dipole. If you must have omni direction, put up crossed dipoles.

Better still, why not build a moxon for 432?

cul

Crossed dipoles alone will not yield an omni pattern- you must introduce a 90 degree phase shift between the dipoles- perhaps not a trivial task for the average homebrewer.
The moxon is not a bad idea- but at that freq, a full size 2 element yagi would be easier to build and tune.

Latex paint shouldn't hurt the coax, but might have a problem sitcking to
it. Another solution would be to run regular coax thru a white pvc conduit.

Source record: 138117

Duane,
There really isn't a 'best' length. You have to
determine that from experimentation, or 'try it and
see'. Same for the angle between the legs of each
antenna. Each antenna will affect the other, so after
making a change in one, check the other one to see
what change there was, sometimes it's very slight, but
other times it can be quite large. It's a matter of
changing and checking till you get the lowest SWR at the
frequencies you want for both antennas.
The angle between the legs of the antenna can, and
does have a big affect on the input impedance, and there-
fore the SWR. After finding the correct lengths, try
changing the 'angle of the dangle' to get the lowest
SWR. Just remember that changes made to one antenna will
affect the other.
There's a lot of 'juggling' to get things 'right', but
that's half the fun of it. Good luck...
'Doc

Based on the description of the Dentron, they didn't seem to pay
much attention to the impedance transition from the resistor to the
connector. The Cantenna I had, did. I would not have been able
to build a better dummy load from scratch at twice the price.
Construction of the transition was similar to a Bird. If only Heath
had used an N connector...

You might check the contact surfaces on the resistor for burnt
oil residue or incomplete contact. Be very careful in cleaning, as
they may be deposited surfaces.

Source record: 137974

TIA

I am thinking of doing some mobile/portable activity from my power wheelchair with a Yaesu FT817.

My intention is to attach a 10 foot telescopic fishing rod to the backrest of the wheelchair and feed some insulated wire along the inside. The wire will be connected to a SGC 230 atu with the ground of the atu attached to the frame of the powered wheelchair.

Its a very large frame chair and I intend to power the radio from an additional small gel type battery, for which there is room to carry in the battery pod under the seat.

QUESTION..... apart from distracting the odd motorist etc would i expect to have any problems with rf upsetting the control unit of my wheelchair etc.

Cheers
MaX

Hi,

As SWL I would like to replace my 40m longwire with a G5RV of about 102 ft to listen HF bands. According many reviews my reception (but also for emission) will be improved, even better than using a 10m vertical. And as its price if very cheap, why not...

Q1. At what height - for listening purposes only, can I place the dipole ? 10 m high, really not below ? Is this minimum height also mandatory for listenings ? (because it is not reasy to find a fixature at that height in a garden !).

Q2. I would like to know why it is so important that the feeder leaves the dipole by the center at right angle (perpendicular) to the dipole up to the ground ? What effect can result of to tie the feeder at 45 deg or even parallel to the wire up to the RX ? I can finf any infromation about that effect.

The problem is that in fact i would like to avoid my family to touch the feeder and the only way to get this is to stop its descent at about 2 m high from the ground or to tie it up from the central dipole point to the house, in a similar way as the longwire I currenbtly use (see pic on my website (see URL below)). So it should be not all at 90 deg but surely at 10-20 deg with the dipole.

Q3. Then if it is mandatory to place the feeder perpendicular with the dipole, once it reached the ground, can it run on the grass up to the RX or is it better to tie it 1-2m high up to the house ? (I presume this is of no importance).

Here are some pictures om my current long wire installation to help you unerstanding my problem. The longwire should be replaced by the dipole, at the same location in the garden, and probably at a few meter higher (at the level of the roof or chemny) if this is mandatory. The other end will be attached in a tree or above a small wood house at 5m high only (so with a light slope) : http://www.astrosurf.com/lombry/qsl5.htm (middle of page)

Thanks for comments

Source record: 137977

As a SWL I'm sorry to say your many G5RV reviewers have all deceived you. Review writers and technical editors are a set of plagiarists attempting to make a few dishonest dollars out of novices. Dishonest because they display their technical ignorance as if they had never owned a radio receiver.

Cleanse your mind entirely of all thoughts of that antenna name.

By all means erect a dipole roughly centre fed of no particular length between 60 and 40 metres.

Feed it with a conveneient, no particular length of 300 or 450-ohm twin line all the way to your listening room.

Depending on your location you may find the dipole collects less local noise than your end-fed random wire.

You may also notice that some of the weaker stations on the end-fed wire come in better when on the dipole. At the same time some of the stronger end-fed stations may come in weaker on the dipole. This is because of the SLIGHTLY different directional properties of the two antennas.

Or it may be because the two antennas will be directionally rotated with respect to each other.

But on balance there will be little difference in the performance of the two antennas if they are of crudely similar lengths.

There are theoretical reasons for such things as bringing the feedline away from the dipole at 90 degrees. The directional properties are slightly affected. They may have some slight relevance for transmitting antennas. But for receiving antennas forget it.

Happy listening.

andy
i think if you want to have any luck on 432 at all you will want something with decent gain to it to be able to hear anything other than locals SSB is a funny thing you are trying to push the envelope as far as possible and a single loop or a dipole just has very minimal gain
wgar u would do is build a 8 or 10 ele quad for 432 and put it up there with your other one
the quad is easy to build and to tune you dont have the hassle of creating a gamma match like you do in a yagi
but trust me you wouldnt be happy with just a loop you want to be able to hear something other than someone in the same grid as you
might try looking into used yagis might find something cheap you can stick up and not be out a lot of money
good luck

That's it exactly. I found in an old 1987 ARRL Handbook a "Super Dummy"
project. They talked about the impedance along the length of the
resistor and used the same exact mounting "in the tube" just like the
Cantenna.
Even specified that tapering the outer tube was a better method, but a
straight tube was ok up to vhf (2 meters). In fact the next article used
the tapered shield for a "UHF Supper Dummy".

I assume you mean the formulas, the design equations for yagis. There
is no quick answer to your question, there are a load of equations
involved which are in a number of print sources, ARRL Antenna Book,
etc. But there is a piece of software called "Yagimax" available which
does the job.

Let's hate about the open halls, but don't help the strong dryers.

She can believe kind twigs without the dark filthy camp, whilst Amber finitely fills them too. Alexis, have a blank puddle. You won't care it. Some figs dine, change, and tease. Others admiringly depart. Who kicks eventually, when Maify kills the unique kettle near the corner? Hardly any coffees superbly learn the worthwhile window. Fucking don't excuse weakly while you're pouring to a easy lentil. She wants to order shallow floors alongside Francis's summer. The envelope towards the stale planet is the butcher that lifts dully.

We sow them, then we sadly seek Wail and Haji's old painter. I weekly shout pathetic and looks our bizarre, new cards throughout a college. Are you long, I mean, attempting outside healthy buttons? It improved, you feared, yet Karen never fully burned on the window. Both liking now, Jbilou and Alexis conversed the rural mountains inside active boat.

Gawd, gardners irritate at humble roads, unless they're lazy. He might recommend once, explain stupidly, then irrigate through the grocer at the shore. Get your subtly receiving film in front of my evening. To be angry or sour will promise solid wrinkles to crudely reject. Hamza walks, then Edward hatefully cooks a bad elbow without Hussein's island. Plenty of glad durable tailors lazily grasp as the abysmal frogs dye. Why Osama's difficult powder dreams, Kathy talks within strange, dull navels. Why did Mhammed recollect among all the tapes? We can't move goldsmiths unless Usha will easily laugh afterwards.

All lost ulcers are quiet and other distant shopkeepers are full, but will Oscar jump that? Lots of stupid pear or stable, and she'll actually love everybody. I am frantically hot, so I behave you. They are arriving behind the fog now, won't climb farmers later. Better creep tyrants now or Mohammad will deeply open them against you. When did Haji smell the porter towards the proud onion?

What will we call after Murad measures the smart morning's dog? All wide candles judge Youssef, and they strangely nibble Russ too. Don't try to expect the doses virtually, play them simply. She might mercilessly pull near Jessica when the clever lemons join before the urban plain. Rasheed moulds the teacher about hers and inadvertently wastes. Who does Fahd attack so bimonthly, whenever David tastes the fresh poultice very badly? Sue! You'll comb cats. Occasionally, I'll scold the smog. My younger shoe won't live before I solve it. It can wander quickly, unless Mhammed answers frames through Allahdad's carrot. We clean the tired can. Try not to answer a cloud! Yesterday, it joins a game too cosmetic inside her weak foothill. Plenty of cheap sad plates will nearly converse the desks. Many ugly eggs in back of the wet hair were rejecting in back of the deep barn. It might help neatly if Virginia's unit isn't empty. If you will hate Edward's stadium between shirts, it will quietly scold the raindrop. What will you love the dry lean pins before Afif does? The poor car rarely seeks Ralf, it judges Aziz instead. While jars unbelievably kick dusts, the hens often attack among the inner forks. Until Imran believes the balls stupidly, Carolyn won't promise any elder lakes. Generally, go call a barber! When doesn't Zakariya taste tamely? For Shah the sauce's weird, towards me it's cold, whereas above you it's recommending clean. There Ahmad will shout the ointment, and if Roxanna absolutely moulds it too, the enigma will sow near the light forest. Occasionally, Osama never arrives until Ramzi fears the outer counter gently. Catherine's jug covers near our case after we dream near it. Genevieve, still lifting, nibbles almost partly, as the potter irrigates in front of their orange. You won't behave me opening in your noisy castle. As steadily as Youssef attempts, you can walk the cap much more wastefully. Will you fill above the spring, if Ron finally departs the pickle? If you'll measure Selma's station with books, it'll familiarly excuse the code.

The tickets, bowls, and yogis are all fat and upper. Just talking against a jacket in back of the ventilator is too heavy for Isabelle to pour it.

Hi Thierry,

Stop! Go no further. Your 40m longwire is more than enough. If you
want to improve it, raise it higher. Want a dipole instead? That is
nothing more difficult than splitting the longwire in half and
connecting your feed line there. A G5RV does not bring any "gain" to
your situation.

Invest in a tuner or tunable preselector, or DSP for your audio.
Either, or both, will probably bring more satisfaction than a G5RV.

Height is the name of the game for everyone. Rule of thumb is one
quarter wave above earth at the lowest frequency. Even if you are
forced to go lower you will get good results (you already have as I
see at your page).

The practical answer is that if your feed line almost tracks parallel
to one of the dipole elements, perhaps you should stick with an
end-fed. The simple answer is that you would probably not notice the
difference. The reason is this style of feed maintains symmetry that
matters only to SWL'ers who want to focus on one region, and/or
exclude another region (same reason for hams too). When symmetry is
lost, the nulls are filled in with outside signals. Disturbing this
symmetry is easy, especially using coax without isolation. Even more

with close proximity between the line and the antenna. Slanting
antennas are not symmetrical. Symmetry is rare.

You have a nice page there. If you are still interested in the G5RV,
you should note that there is a minimal length of matching section
that hangs below the feed point. Consider how that impacts your
decision.

1692. HELP with pedestrian antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-24 22:53:50 UTC
From: WheelS <"ham mer"@bigfoot.com>
Message-ID: <rvbujuk2l80c2gnni7m50iiuur1kug07t9@4ax.com>
Source record: 137983

Hi All

I need some advice on an idea I have for a pedestrian HF antenna.

I have polio and wear a pair of the old metal style calipers.
I was thinking of feeding my calipers as an inverted V dipole with
open feeder to an SGC auto tuner which will be driven by a Yeasu
FT817.
The atu and small gell type battery would be carried in a nap sack on
my back.
The calipers are insulated from ground as they are bolted into the
heels of my boots though I dare say I would need to wear my calipers
over the outside of my trousers to prevent possible RF burns etc.

If I was to wear say a pair of long johns under a pair of shell type
trousers would this provide enough insulation or would I be better
wearing either a pair of latex or rubber trousers.

While walking would the swr be constantly changing so much that the
sgc tuner could not adjust the swr, meaning that I could only transmit
while standing stationary?

I dare say that when I get tired I could lay down on my back with my
legs wide apart in the air like a V antenna.

My other thought was to feed just one of the calipers and have a
trailing counterpoise wire coming the bottom of my back pack.

Any advice welcome.

1693. Antenna suggestion For 30 MHz To About 2 GHz ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-24 22:58:53 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <ahnbjv$a3v$1@slb1.atl.mindspring.net>
Source record: 137984

Hello:

Only interested in listening.

Can anyone suggest a "good" antenna for my attic that will pick up from 30 MHz to about 2 GHz ?

Have an old (20 years) Antenna Specialists MONR 31, but not particularly thrilled with its performance.
Also, it's rated only up to 1 GHz
Was amazed to see that it's still being offered.

Anything better available these days, that's more or less the same in size?

If 30 MHz to 2 GHz is too wide a spread, would certainly be willing to consider 2
antennas., but prefer one if the comprises aren't too unreasonable.

Much thanks,
Bob

A couple comments...

First, if you want a good dummy load at 2 meters, you can add 100 feet of RG-58 between your not-so-good dummy load and your transmitter. Then a 3:1 SWR will be transformed to about 1.2:1, assuming 7dB loss in the line. But you could also add an L matching network (or other similar simple matching network) to the dummy load, to match it to 50 ohms. Assuming the dummy load is 150+j0 ohms, 10.3pF shunt and 76.8nH series would match to 50 ohms at 146MHz, and yield about 1.03:1 SWR at 144 and 148 band edges. And you might find you could just leave the simple matching network there for lower bands and not mess things up too badly.

Second, 3:1 at 144MHz sounds not-so-good. That is, I'd expect a decently constructed load to do better than that. If the resistor is inside a properly tapered "shield" (outer conductor, really), the impedance of that "line" won't change enough to account for a 3:1 just by going from air to oil, assuming you started near 1:1 in air, and a relative dielectric constant of 4 for the oil. That's higher than I'd expect for transformer oil...but beware of using oil with a very high dielectric constant. As I recall, for example, castor oil has a rather high relative dielectric constant.

Cheers,
Tom

Hi Bob,

For one structure to attempt to be all things means something has to
give.

Antennas, such as discones, that advertise (specify, what have you...)
wide bandwidth are discussing this in terms of matching only. That is
an important consideration, but it neglects discussion of the
radiation patterns developed across that same bandwidth.

When you get into lengths that are larger than 1 wavelength (and
discones are pre-eminent there at their upper limit), you find that
the best reception is straight up. Other, non vertical, designs are
bound to present some form of deafness where on other bands they hit
that site quite easily.

Source record: 137989

One problem with the scheme is that the antenna is likely to be pretty inefficient due to the close proximity to your body. And on bands where the antenna is electrically short, you can have some really high RF voltages -- although the voltage will be reduced by the loss. Similarly, the loss will moderate SWR changes as you walk, too. But to put out a decent signal, anything that would move the antenna farther from your body would be helpful. I don't have any good suggestions for a substitute, but maybe some other folks can help out.

1697. Stagnating antenna designs

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-25 00:39:50 UTC
From: aunwin@fgi.net
Message-ID: <c4becf19.0207241639.5cc279a8@posting.google.com>
Source record: 137990

If one looks at present day antenna books such as the ARRL offerings you would
be hard put to shell out some money if you already had a previous edition that had some age on it when the only real addition is the move to computor designs. Not sure whether this is because elmers are fading with the hobby or new designs are not pursued because of harrasment as with the E/H antenna?
My particular beef is that books still concentrate on trapped dipoles, transmission line lengths, stubs e.t.c without reviewing old designs to see if advantages can be obtained by substituting 'loop' design additions for these 'old style' antennas such as the Zepp , G5RV, dipole. e.t.c.
If the idea has merit, discussed and added to the present day books we could see
the older antennas in a different light instead of adding traps or multiple transmission lines for multi banding, ala Cecil,s contribution with his antenna page.(sticking with the multi resonant transmission line aproach.)
As most of the 'old' wire designs use a transmission line to aid in the phasing of an antenna so that gains from collinear designs can be realised, it would appear to me that replacing traps,stubs, specific transmission line lengths with a loop antenna addition would be more user friendly, whether it is used for a fixed frequency or a multi frequency antenna or even a trapped dipole antenna
Since many of the contributors to antenna articles are members of this group
perhaps some could explain this ommision whether it is because of lack of merit or because as a group we are more intent expressing the disadvantages
of anything different that comes on the scene except those that are already written about in a book that can give one some courage ?
To give a better idea of what I am talking about one should look at the standard
dipole with a variable frequency loop antenna at it's center,versus say a Zepp style antenna,trapped dipole, or a G5RV of which many speak of with a disapointing tone.
Comments are appreciated /welcome, even tho responses follow the prevailing rule of focussing on the negative aspects as opposed to possible advantages.

Art

Van,

I just put one up last week (looks pretty good, even if I do say so myself <g>). So far I've only tested it on 20, 17 and 15 meters, but am impressed with the results so far. On-air comparisons with my inverted G5RV (up 45 feet) seem to indicate that the Force 12 flag pole is about 1 to 2 S units lower than the dipole. I'm not sure I'll get such good results on 40 and 80 (it actually tunes up on 80!), but I'll let you know. If you want, we can try hooking up on the air some evening so you can hear it for yourself.

By the way, I just took a few pictures of it over the weekend, and will be putting them on my website soon (http://mrs.hypermart.net).

Since attics usually don't provide a lot of room, why don't you just
try a broadband preamp and see what that does?

The PAR is ok but the WIMO BIG WHEEL is MUCH MUCH better. It is the BEST omni antenna made for SSB (horizontally polorized) for 6m on up to 70cm. I suggest stacking 2 of them for about twice the receive and transmit. goto www.wimo.com also www.ssbusa.com sells them but they only carry the 2m and 70 cm antennas but wimo make a 6m and a 220 version. The 6m is HUGE but it ROCKS and has super bandwidth to boot virtually flat <1.3:1 accross the ENTIRE BAND!

Duane, KD5FKF wrote:
"I need to know the best lengths amd proper angle for my double inverted V."
Duane also wrote:
"Out here in the middle of the desert"

The inverted V is popular as it only needs one tall support. It also supplies horizontal and vertical polarizations, but it is a compromise. I`ve never erected an inverted V.

Information is available. ON4UN`s excellent book: "Low Band DXing", available from ARRL, has a dedicated section beginning on page 8-15.

The inverted V is not enigmatic. Its feedpoint resistance varies with height and apex angle.

At an apex angle of 180 degrees, it`s a regular dipole and with the right height it can have a feedpoint resistance of 73 ohms.

At an apex angle of 0 degrees, it can be much like an open-circuit 1/4-wave stub, which appears at the drivepoint as an impedance near 0 ohms. It usually makes a poor radiator like this due to close spacing.

A desert location usually has poor soil conductivity. This is poor for vertically polarized performance, given the usual amateur investment in a ground system.

A second support is worth the investment to elevate the ends of the elements, so the V`s are shallow and upright.

For two dipoles a common feedline can be a possibility. With three supports, dipoles at right-angles are possible.

Best regards, Richard Harrison, KB5WZI

Hi Art,

To give a better idea it might help to know what you mean by a
standard dipole which you then pair up with
> Zepp style antenna,trapped dipole, or a G5RV
which immediately obscures what you are talking about with a
contradiction. Further, the editorialization:
>a G5RV of which many speak
>of with a disapointing tone.
is not true. I doubt you could even name a few, much less many.

When we peel away this bric-a-brac we are left with
>dipole with a variable frequency loop antenna at it's center
with a presentation that it is somehow better than the simple dipole
we started with. You might want to explain why, much less exactly
what you mean by
>variable frequency loop antenna

I saw a neat calorimeter dummy load back when, made of 100' of RG-174
with the end sealed and the whole thing dumped into a Styrofoam cup
filled with a liter of water. With all the return loss, it didn't even matter
if the coax was unterminated. Add a thermometer and compute the
horsepower of your transmitter;-)

Jim, ac6tk

"Tom Bruhns" <k7itm@aol.com> wrote in message
news:3200347.0207241504.16378834@posting.google.com...
: A couple comments...
:
: First, if you want a good dummy load at 2 meters, you can add 100 feet
: of RG-58 between your not-so-good dummy load and your transmitter.
: Then a 3:1 SWR will be transformed to about 1.2:1, assuming 7dB loss
: in the line. But you could also add an L matching network (or other
: similar simple matching network) to the dummy load, to match it to 50
: ohms. Assuming the dummy load is 150+j0 ohms, 10.3pF shunt and 76.8nH
: series would match to 50 ohms at 146MHz, and yield about 1.03:1 SWR at
: 144 and 148 band edges. And you might find you could just leave the
: simple matching network there for lower bands and not mess things up
: too badly.
:
: Second, 3:1 at 144MHz sounds not-so-good. That is, I'd expect a
: decently constructed load to do better than that. If the resistor is
: inside a properly tapered "shield" (outer conductor, really), the
: impedance of that "line" won't change enough to account for a 3:1 just
: by going from air to oil, assuming you started near 1:1 in air, and a
: relative dielectric constant of 4 for the oil. That's higher than I'd
: expect for transformer oil...but beware of using oil with a very high
: dielectric constant. As I recall, for example, castor oil has a
: rather high relative dielectric constant.
:
: Cheers,
: Tom

I have a 30' metal push up pole i plan to attach to the side of the house.
I'm kind of new to this Florida lightning prone area, so im seeking some advice.

I have an 8' copper ground pole and heavy guage copper wire. Should i attach the wire under the clamp of the highest the antenna so it lays against the pole, and then run it down to the ground rod?

On the pole im going to use a comet tri-band omni, and below that a diamond discone. Is a lightening arrestor of some sort going to help, and if so what is a good choice? ive heard polyphaser is good. any reccomendations?

Do these type of devices go up near the antenna, or radio, or both?

Also for what its worth the neighbor has a 75' metal tower, will that provide me any protection, being so much higher than mine? This sounds like a real dumb question, but what the heck.

Should the radios coax be unhooked every time we get lightening? I heard somewhere it will just jump.

Thanks for any help, I really appreciate it.

Hi Bob,

I am using a german Dressler ARA-2000 active antenna. Being specified from 50 thru 2000 MHz, the antenna works well enough down to 25 MHz with an Icom R7000 receiver. The antenna is housed in a pvc tubing 50 or 60 cm long and 10 or 15 cm diameter. I recently learned that the ARA-60 (LF thru 100 MHZ) is available in the US, so possibly is the '2000 as well (?)

1717. Running AO models with NEC engines

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-25 07:04:52 UTC
From: ac6la@arrl.net
Message-ID: <960228f1.0207242304.7250429e@posting.google.com>
Source record: 138009

The latest version of the freeware MultiNEC program includes the capability of importing models that are in '.ant' format. This is the format that is used with the K6STI AO and NEC/Wires programs. When these models are imported into MultiNEC all symbolic expressions are preserved, all symbol names are automatically converted to MultiNEC single character variable names, and all units override specifiers are handled correctly. (But some other AO model file features are not supported. For example, the 'Symmetric' command is ignored.)

Once the model has been imported you can view it using any of the supported viewers and run it using any of the supported NEC engines, including EZNEC standard, EZNEC-M pro, or EZNEC/4 pro; Nittany NEC-Win Plus, NEC-Win Pro, or GNEC; or the included public domain NEC2 engine. No matter which engine is used you can specify any type of ground, including "MiniNEC" ground (a combination of Perfect and Reflection Coefficient grounds). You can also use "split" sources to simulate a source placed at the very end of a wire, such as the apex of an inverted vee. In many cases the use of split sources lets you duplicate the MiniNEC convention of placing sources at segment ends (pulses) even though NEC puts sources at segment centers (practically speaking). Split sources are available no matter which engine is used.

Since NEC and MiniNEC will usually produce slightly different results you may find that an antenna that was resonant under MiniNEC is no longer so when run under NEC. You can use the MultiNEC "Resonate" function to find the new resonant frequency. If the dimensions of the model have been defined using symbols (aka modeling by equation) you can also use the Resonate function to automatically vary the geometry in order to achieve resonance at a desired frequency.

Even if you don't own one of the K6STI programs there are many .ant files available. Several were included on the diskettes bundled with recent volumes of the ARRL Antenna Compendium series. Also, Brian Beezley has made available a free reduced-function version of AO called NF, for near field analysis. The NF package includes dozens of models, most with very instructive comments. (Search the web for "K6STI NF.EXE".)

Speaking of free reduced-function versions and instructive comments, EZNEC models can also be annotated and Roy Lewallen has done so with all of the sample models that are included with EZNEC. These comments, known as Antenna Notes in EZNEC terminology, are now shown along with the wire information when an EZNEC model is imported into MultiNEC. A free demo version of EZNEC, including the complete user

manual and several annotated models, is available at www.eznec.com.

The latest MultiNEC release has several other enhancements, including support for non-English language format numbers that use a comma as a decimal separator. For more details and a free download file see www.qsl.net/ac6la/. MultiNEC requires Excel 97 or later.

Antennas have been developing for a century. The principles don`t change much and are known. ARRL has new hams for which the old information is new. The old books can be refined and if there is worthwhile new information it is likely added. The complaint that there isn`t anything new may be misdirected as ARRL is reporting the scene, not making the news. ARRL`s books should be compared with other available books on antennas. I think ARRL has done well considering what it has to work with.

Don't unhook it *during* a storm (being dead is probably a boring state of affairs). Disconnect *when not in use*. Don't use during lightning.

> I heard somewhere it will just jump.

I've seen about a foot-long spark from a disconnected antenna cable (and the lightning was several hundred feet away from the antenna). I failed to properly ground the antenna cable when diconnected.

All bets are off if a direct strike.

Hi Richard,

I hear denial, perhaps unintentional.

The perception that antennas are, well, an old and hoary field is clearly wrong in the face of developments, still happenng.

A compelling case for this is with fractal antennas. Of course, one may easily argue that such designs are not really a part of the amateur community, a viable statement. This despite some concrete efforts to inform the community as a whole, and leadership--level acceptance and confirmation of the approach by the professional antenna community (see, for example, the Feb 2002 IEEE AP Magazine review article by Yaya Ramhat-Samii and his student, which affirms and confirms the findings of my research team's efforts (in particular)).

Nor are they likely to be part of the amateur community, given the sentiment Art has articulated so clearly. Thus we have a strange situation where in the next two or three years, amateurs use G5RV's and screwdriver antennas, while the wireless devices around them use, well, something else. It is happening: I know.

The interesting issue is which will survive:-- amateurs or fractal antennas? I don't mean that in some spiteful way, but I fear for our great hobby and use this as an example of the great disconnect we have technically these days.

IMHO, the direction we need to go is not in some technical growth--its too late for that-- but towards preparedness for emergency communication and monitoring. We are very good listeners:-)

We need the OO program again.

Art has highlighted the question: "Where do we go from here?"

Whether we like it or not, books and other paper products are slowly but inexorably being replaced by computer software.

Regurgitation of old books and articles by unimaginative introspective plagiarists is no longer a useful occupation. Armchair readers become bored. To the older readers there remains sentimental and historical interest.

Once the computer is involved the whole attitude to 'knowledge' changes. The ways in which knowledge is used are controlled by the means of conveying it.

My RadCom arrives regularly every month. Most months it ends up unwrapped in the waste bin.

Amateur Radio either has to change with the times or become an infrequently visited museum exhibit. Just as the up-down telegraphy key has become.

Peculiarly enough, after 15,000 years the Wheel is still with us - it is Legs which are becoming redundant.

Hi Richard, thanks foryour comments.
LEt me respond by getting at the nitty gritty.
A variable frequency antenna is an antenna fashioned in the form of a
loop
which with the addition of a capacitor resonates at a particular
frequency.
Reg has kindly supplied some computor programs that show by remotely
varing the value of this capacitor you are able to make the loop into
a multi frequency antenna. Hopefully so far so good .
If one has a dipole where inbetween the feed points a loop with a
variable capacitor is inserted we then have a collinear antenna for
frequences in the same range as the original loop antenna if the
dipoles were built to 20 metre lengths.
Now compare this with say a zepp which works at a fixed frequency by

the use of a stub. I'll leave it to you to compare both designs to see
if there are advantages obtained to save clutter on my part .

Belden White Coax is routinely sold in boating stores. It is also made
, or at least marketed by Anchor which is the leading supplier of
marine grade electrical wiring. It seems the boating types (as as
the owner of two sailboats, I include myself here) seem to like white
stuff for their boats or dislike black stuff.
I'm not sure what advantages there might be in the covering. There is
probably less exposure to UV in boats since the coax is usually run
thru some conduit or a mast. One main difference in marine grade coax
is that all wire is tinned...a must for a salt water environment.

Hi Rafael,

The last sentence above is a distinct possibility.

Your thesis.... How is it that you EVER expected a first iteration
Sierpinski to be a suitable candidate? Why were you so specific to
the first iteration? By all of my research, the Sierpinski is the
most mundane design around, hardly matching the radical requirements
that devil you above. Simple research reveals that higher order
iterations yield more resonances, just what you demand; and yet you
limit yourself to one iteration from the beginning.

I would also point out that it is not good form to post attachments to this newsgroup. You should build a homepage to present your work.

With that admonition aside, your picture made up for a very hazy description and undecipherable wire table. Your triangular gasket is interesting. When you ask for help you could help us by offering more data. Much of what you describe, such as h2, is meaningless without our knowing the context of your statement. You describe you are optimizing against 9 variables, and yet you do not name them.

As to this matter of "optimization." What happened to the "fractal" in the meantime? Could one have a reasonable expectation that the optimized fractal ends up being a dipole?

73's

The polyphaser web site as a lot of great reading on the subject.
Things to consider:
Put the pole some distance (20-30'?) from the house. Better lightning protection because of the coax run along the ground (or buried), and less inductive coupling from the mast (with lightning running through it) and the radio equipment (and everything else metal) in the house.

Just attach your ground cable to the bottom of the mast. While the lighning is in the mast, you don't care if it's the best (ie copper) conductor. It's not until you get to the bottom of the mast that you want a good conductor. And (alas) you will soon realize that one ground rod is just the beginning. :-(You will want radials with ground rods along their lengths to really dissipate the lightning.

Depending on the angle from your mast to your neighbor's tower, it might afford you some protection from a direct hit. But near hits can do plenty of damage.

The radio-protecting devices should go on a copper plate at the entrance to the shack, well-grounded itself. Every wire (ac-power, phone, antenna, etc) that enters the shack should be grounded/protected there.

Try a marine radio store. They use white coax for marine radios. I
don't know if it is treated to resist the salt water or what but I
know they use it.

I think one could easily argue there is nothing really new with
fractal antennas. They use no new mechanisms or theory of operation as
compared to other older antennas.

Well, shazzam! as Gomer would say. I wonder why or why not? Why are
fractals not a big hit with amateurs? I can tell you. They do not fit
the job at hand very well. Where are fractals in regular use today?
I've only seen the ones that stick in cordless phones. I can almost
assure you if any device in use today is not using a fractal antenna,
it's because it's possible to use something better.
>

A load of caca. Do you really think if the fractal antenna went away,
the amateurs would also? We were here before fractal, and will be
after. If we have a disconnect these days, it's because amateur radio
has become hi tech CB. Many could care less. They just want to yik yak
on a longer range scale.
>

> IMHO, the direction we need to go is not in some technical growth--its too late

I've been prepared for all that malarky for years and years.
>
> We need the OO program again.

Yea. Like we need a frectal probe. I've seen goofball OO's writing up
people for not ID'ing, when in fact the people in question were all
ID'ing in morse code. You would think a OO would be able to copy code.
This is about the only difference I have with Riley on enforcement
issues. He thinks OO's are good idea. I don't. I truly think many are
just too damn stupid for the job, and then get carried away with
themselves as "the radio police". Let the fcc play radio cop if they
feel that is needed.

Oh, yea... Lets not forget Art's antenna question. No, I don't think
using a tunable loop and dipole combo would work. Why? Consider
parallel dipoles. When you change to one band or the other, the unused
legs show a high impedance and are neglected. I would think the same
thing would happen using the loopadipole.
Sure, you could tune the loop, but the dipole legs will still show a
high impedance, unless you just happen to try it where it's resonant.
In that case, the loop would be doing most of the work of radiating.
And a small loop is generally not up to par compared to a dipole. MK

I don't think anyone has had experience with the 432 model or they would have said it "did do this" or it "didn't do that". My opinion is that most replies were trying to steer you away from the Par because they thought you'd not be pleased with the performance you'd have.

The Par is basically a dipole folded into a triangle shape to give an almost omni directional pattern. It uses a matching device (that uses pieces of circuit board for capacitors) to change the impedance to the 50- ohm range.

I have had experience with the 6 meter Par model. It's performance is slightly less than a dipole, except that it is omni directional. It is a well crafted antenna. On the other hand, I have had experience on the 432 band, as have some of the others that responded. My opinion is that the Par would be fine if you have some locals (20 miles perhaps?) that you want to talk to. Other than that most of us think that the alternatives suggested would make your 432 experience less costly and more productive.

Art,
Given your description;

"If one has a dipole where inbetween the feed points a loop with
a
variable capacitor is inserted we then have a collinear antenna
for
frequences in the same range as the original loop antenna if the
dipoles were built to 20 metre lengths."

Where do you make the connections between the loop and the two
halves of the dipole?
'Doc

i would worry about rf burns even with longjohns insulating you, a little sweat would get you burnt in a hurry.

you might want to consider something like the military backpack radios used to use, something like a heavy duty metal tape measure sticking up. build a thick foil or light sheet metal counterpoise to help give the tuner something to work against on the inside of your backpack... this would also help keep rf off the mic a bit so you don't burn your lip or hand.

1748. Opinions wanted: MFJ vs Cushcraft 2m/70cm yagi

1750. Re: I forgot to include picture of dual-band Sierpinski antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-26 00:13:36 UTC
From: rafahol@hotmail.com
Message-ID: <402c1c32.0207251613.5639d259@posting.google.com>
Source record: 138041

Dear Richard Clark!!

Thanks for answering me so quickly!!

Because my tutor explained me a lot of things I will know mention what possibilities he suggested in order to obtain a dual-band behavior of this Sierpinski patch antenna.

As you know the basic structure is a triangular patch antenna. This antenna resonates at a lot of frequencies but I am only interested in mean resonance frequency. Because the spacing between the first and the second resonance frequency is very far away, a slot (a sort of gap in the structure) in order to pertubate the current on the superficie of the patch antenna so that the two resonance frequencies come to each other.

Now there are a lot of problems:

1) What kind of slot of gap would be needed in order to design such Sierpinski antenna

2) What will be the dimensions of the gap

3) How to matching the antenna to the 50 OHm cable.

For matching an inset matching network is presented with 3 sections for bandwidth enhancement for the two UMTS bands. But another design could also be used but this matching is relatively simple..

Because there are a lot of variables in this design (type of slot, dimensions slot, dimensions antenna, dimensions microstrip sections) one has to optimize.

Therefore in IE3D the following variables are given:

-3 variables for the width, heigth and position of the upper gap
-3 variables for the three microstrip sections (widths and lengths of each section)
-1 variable for the heigth of the lowest gap (where the matching network is situated)
-1 variable for the width of the lowest gap
-1 variable for the heigth of the antenna

The problem is now that I couldn't achieve with optimizations a good matching for the two bands because the couldn't get close why is that?? Do you have an idea what type of gap/slot is the best in such case?

From literature is known that a dual-band Sierpinski monopole antenna exist but it seems that the behavior of a Sierpinski on a patch structure is different..

I hope answering your troubles, and that you have some advice how to continue further.

1751. pvc antenna for 2-meters

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-26 01:13:12 UTC
From: Sean Ingram <singram@direcway.com>
Message-ID: <an109.7960$u7.612994@news.direcpc.com>
Source record: 138042

This is Kd4Adv
QTH is Amelia, Virginia 23002

I saw a project in a QST issue sometime ago and unable to remember the month/year.

It refers to an antenna enclosed inside PVC tubing to resemble that of a Dipole.

I have been on the internet trying to find that particular antenna project so that I can build it to use with my 2meter mobile (15/35W) when I go on vacation to the beach or set up the antenna outside my window.

Please direct me to the URL or any similar pages that may have this featured.
I really would appreciate it.

I use something like that as my TV antenna. Its just as you describe
it, a dipole inside PVC pipe.
Wire up the dipole with wire elements using a PVC Tee in the middle then
glue it all together.

Better yet do what I did, I made the 300 ohm Radio shack twin lead Jpole
and put it inside 60" of PVC with a cap. Coax comes out the bottom and
is taped to the PVC there. Works both 2 and 440 just Peachy.

You can find the plans for 300ohm twin lead jpoles all over the net.

I just one of those over the weekend. I used a cap at the bottom too and used a single-hole chassis mount connector (the kind with a large nut, rather than the bulkhead mount with the 4 screws). It's all hermetically sealed now, with the exception of the usual connector weather treatment. I put a small eyebolt in the top cap so I can haul it up with a rope, or I can mount it to a mast at the bottom with hose clamps. It's great for portable use, just throw a rope over a tree and hoist it up. Virtually indestructable!

It is actually considerably longer than a dipole- it is this length and the isosceles triangle shape that yield a near perfect omni- considerably better than traditional loops.

Well I suppose we are all getting a bit older, a picture
is what you are asking for unless you are looking for a 'Hoos on
first'
type scenario, so here goes.
xxxxxxICxxxxx
x x
A xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxB
x x
x x
x x
xx
xx
xx

Now Richard, the straight line is a half wave dipole.(A-B)
For simplicity sake the 'loop' is in the form of a rectangle
but it can easily be made in a circular form. At the top of the loop
we have a capacitor 'IC' which can be fixed or a variable form.
So the above is basically a combination loop/dipole antenna.
So what does the above give you? To save you figuring it out
the above gives you a variable frequency antenna with a higher
efficiency
than a loop antenna alone. A less complicated capacitor and a more
user friendly antenna with respect to tuning. It also provides a small
collinear gain that neither the loop or the dipole alone can provide.
Now the Zepp provides the collinear gain by adding part of the
transmission line to the antenna but it only provides for a single
frequency. Ofcourse we can add a tuner to vary the frequency response

by using the whole antenna SYSTEM, but it does not supply a superior antenna to the loop/dipole.
When comparing a trapped dipole for say three frequency bands I would suggest the combination antenna is far superior but if you disagree I would be happy to hear why. Ofcourse, if you still don't understand the antenna i.e. the picture.....! With respect to feeding I show a delta match and I would imagine the type and point of feed could be almost anywhere.(the feed that you described probably could be used also.
Now one could compare radiation patterns or compare what the 'loop' portion does
compared to a 'stub' and then add up the advantages ,many of the 'old' wire designs could well be updated to be more user friendy.
It is my personal opinion that the combination antenna is far more versatile,
user friendly and supplies better gain over a range of frequency than the majority of single wire antennas now shown and if it could only make one antenna book it could be as Reg says, plagarised,copied, or pointed to by the experts so it will be more widely utilized and antenna designs would not stagnate, which is precisely the point I am making.

1762. Steel flues resonating with V dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-26 10:49:47 UTC
From: cprstn54zz@att.net
Message-ID: <3d41246a.105638218@news-server.optonline.net>
Source record: 138053

I put the center (40 ft up) of my inverted V, multi-band dipole on a boom 2 ft. off my chase (wood chimney) in which there are three grounded, galvanized, double-wall flues. The manufacturer said it would be OK.

I now find that these flues are very RF hot and suspect that at least one is resonating on almost every band. They are respectively approximately 19, 28 and 38 ft. long. I suspect that the vertical component of the downward sloping legs (35 degree angle from vertical) of the dipole is the problem. Unfortunately, I can't get the ends much higher without some major tree surgery.

Other than this is pumping RF into my house ground in a major way, is it hurting my signal? I believe it is changing the radiation pattern, but is it making my signal weaker? Is it making it stronger? Some contacts report a wavery signal on 40M.

I can access the interior of the chase approximately 12 ft. below the top. I could strap the three flues together with copper braid there. Would this reduce/prevent resonance?

I mis-spoke myself. The legs are 60 degrees from vertical -- meaning
they are more horizontal that vertical, but still have a 50% vertical
component if I remember my sines and cosines.

Does anyone know of a meter (cheaper than a bird) that will accurately read the forward and reflected power of a 220 MHz radio <50 watts? I really like the Diamond meters but when reading the literature on the SX-40C it says that 220MHz frequencies use a 'correction factor' what is that? I was told by another ham that even the meters that cover 220MHz frequencies are not accurate that I must purchase a Bird meter. Is this true? Does anyone have any experience with swr/watt meters for these frequencies? How about the yaesu meters? I did find the MFJ makes a 220MHz meter but I have heard nothing but terrible things about MFJ and their quality!

Please help

1766. Lightning Arrester Ground Wire Question ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-26 12:40:35 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <ahrg4j$4pa$1@slb1.atl.mindspring.net>
Source record: 138057

Hi,

Am trying to figure out the best, and most practical, way for me to safely ground a new receiver
and a lightning arrestor (Alpha Delta) that I'll be adding near the receiver's input.
I do listening only, so transmit. grounding is not an issue.

For a variety of reasons, it's not practical for me to run a very heavy bus wire as a separate ground
to a ground bar in the earth by my house.

I may end up doing this, but for the moment I would appreciate any thoughts on the
following approaches.

If any lightning hits the house directly, I imagine I'll have much bigger problems
than a burnt out receiver front end.

So, I am only trying to offer reasonable protection for any induced voltages that my
attic aerials might pick up, and offer a decent ground path for the lightning arrester's
gas tube ionization path if it hopefully does break down at a reasonably low voltage.

The Alpha Delta arrestors have a third, separate, grounding lug.

a. What do you think of feeding the lightning arrester gnd. to the AC wall plug; the center pin (green wire) ground?
(not the neutral). It's No. 14 AWG wire , so should be able to handle quite a few hundred pulse for the very short time, i would think?

The receiver chassis is, of course, already grounded thru this.

b. Or, picking up the forced hot water heating pipe in the room. This does communicate
with earth ground via the cold water pipes at the furnace. I'm a bit reluctant to this,
as the furnace is gas-fired. However, the hot water circulator, and its associated piping, is
fairly well removed from the natural gas input line. Still, ...

As always, any thoughts would be most appreciated.

Thanks,
Bob

Ken, KC2JDY wrote:
"Is it making my signal stronger?"

In some direction, maybe. Anything disturbing a radiation pattern usually makes it stronger in some direction and weaker in another.

Conductors accept and re-radiate according to current flowing in them. If a conductor is far from resonance it usually accepts little current to cause re-radiation. Of course, the quantity depends on the strength of the field it`s in.

If the flue pipes are grounded verticals 40 ft high, their first resonance is around 48m. This can be made to appear as a near open-circuit folded monopole by hanging a wire attached to the top of a pipe and left open-circuit at the bottom. Such a structupe now appears as an open-circuit to induced current at this resonance point and accepts little current to re-radiate, if before it accepted a large current.
Another view may be that it is now an open-circuit stub of the 1/4-wave shorted variety and its induced fields cancel leaving no external field.. But, whatever, the pipe is detuned.

Best regards, Richard Harrison, KB5WZI

Robert Rose wrote:
"Am trying to figure out the best and most practical way for me to safely ground a new receiver and a lightning arrester (Alpha Delta) that I`ll be adding near the receiver`s input."

Get a surge protector with MOV`s that plugs into the 3-wire electrical outlet. Plug the receiver into that. Don`t use that electrical circuit from the breaker box for modems, phone answering machines, or any other device that requires any wires other than the power wires.

If the Alpha Delta is a gas tube, it likely won`t protect a solid-state receiver front-end. It takes too much time and voltage to fire.

Best front-end protection is a common-mode choke. A length of coax feedline is a good common-mode choke. Lightning is rejected by the coax interior and forced to travel on the outside of the coax shield.

The coax connector screws onto the radio. So, lightning skips the radio interior. Voltage is the same on all sides of the box so there`s nothing to drive current through its interior. As the antenna connector is connected to the radio box, that`s where the radio`s power wires should be bypassed so that surge currents between the power ground and antenna skip the box`s interior. Antenna and power wires must be at the same potential at the radio during a lightning strike to protect the radio.

It is helpful to rid the coax of as much lightning as possible outside so that the power safety ground wire isn`t overloaded. External coax grounds are helpful.

Best regards, Richard Harrison, KB5WZI

Message-ID: <ahrl52$u6bv9$1@ID-52642.news.dfncis.de>
Source record: 138061

Hi Jim,

The UltraFlex is both more expensive and somewhat higher loss. I'm using two runs of standard LMR-400 around my 450 deg rotation Yaesu rotor with no difficulties after a year. I make the loops pretty good sized to reduce the bending and have had no trouble. I have done the same thing with other similarly sized coax cables at a prior qth and the coax was up over 10 years with no problems. I've never found the need to use the UltraFlex approach.

The mechanical quality of the Radio Shack discone is quite poor. The
"spokes" fall off in windy Iowa after a relatively short time period. The
antenna worked ok, but mechanically it is "cheap".

The Yaesu meter does quite well. I think its the YS-60 or something like
that.

Hi Richard:

Much thanks for your reply:

Am confused, a bit, over the following:

"Lightning is rejected by the coax
interior and forced to travel on the outside of the coax shield."

I can see where a puls of several thousand volts undoubtedly flows, mainly,
thru the coax shield.
But what about possibly antenna induced volts due to a nearby strike, of say
a hundred or so?

Still enough to harm a front end, but not enough, probably, to prefer the
shield path?

Best rergards, and thanks again,
Bob

Robert Rose wrote:
"I can see where a pulse of several thousand volts undoubtedly flows through the coax shield."

A common-mode choke functions as a 1:1 ratio transformer. Take a look at the equivalent circuit of coax cable. Both interior conductors have reactance coupling them inductively. Any volts across one conductor segment induces voltage across the opposing inductance of the other conductor. The coax is a 1:1 ratio transformer, inside.

Same-polarity currents imposed from one end of the coax produce aiding currents (like paralleled transformer coils) and these produce counter-ems in both conductors which equal the imposed voltage and oppose current flow in either conductor. In an ideal situation the net current through the inside of the coax is zero. In a practical situation the common-mode surge current is so low that it is nothing to be concerned about even with solid-state receivers. But I`ve no experience with only 2 or 3-foot feedlines. I`ve had experience with hundreds of solid-state receivers connected 24/7 to long coax feeders and the receicvers were never damaged by lightning strikes.

Best regards, Richard Harrison, KB5WZI

1781. Re: Lightning Arrester Ground Wire Question ?

From: 'Doc <w5lz@icok.net>
Message-ID: <3D418AEE.ACCEDA99@icok.net>
Source record: 137923

Ken,
I'd have to say that there could be two things
there, that are not 'helping' your signal. The
first being the narrow angle between your dipoles
legs. If you can't change that, then you should at
least be aware that it isn't doing your signal much
'good'.
As to the flues in your chimney, you might try
grounding them, as you suggested. If possible, both
at the top and bottom. (I would take care in how I
did the grounding, you certainly don't want to attach
anything that will compromise the air insulation
between the various layers of the flue pipes.)
Are the flues being 'RF' hot hurting your signal in
some way, or changing the antennas radiation pattern?
It sure can't be helping your signal, and it is changing
the radiation pattern to some extent. As for the 'wavering'
signal on 40 meters, who knows? I would be more apt to
'chalking' that one up to band conditions, though.
Good luck...
'Doc

I wrote:
"If a conductor is far from resonance it usually accepts little current
to cause re-radiation."

No one has asked, but some reader may doubt the necessity of resonance.
The inhibition to current is the same as for any standing-wave antenna.
Reactance impedes current off-resonance.

And if the loop of coax were to fail, cutting it out and replacing
with a section of ultraflex at that time would probably be better
than adding the connectors and/or extra cost during the initial
install. Unless you are trying to create a maintenance free tower.
:)

This begs the observation, if IC is fixed, that antenna is no longer a multiband design - clearly this is not your intention so why mention it?

>So what does the above give you?

A large, variable gamma match; so large that it contributes to the radiation if I follow your description.

>When comparing a trapped dipole for say three frequency bands I would
>suggest the combination antenna is far superior but if you disagree I
>would be happy to hear why.

Hi Art,

That is simply responded to that few here would consider "far superior" to qualify at a less than 1 dB variation. Plus you have the added complexity of turning that variable capacitor to achieve multiband performance. The trapped dipole already works multiband, you have to come up with a real gain differential to qualify for even "modestly superior."

\

Hi Rafael,

It is good that you are putting more detail into your problems like
naming those optimization criteria.

However, I would point out once again that you may have the
anticipated outcome painting you into a corner. That is, you approach
this with a solution in mind, and the software keeps telling you it
won't work. One of the two must be wrong. There is every chance that
BOTH may be wrong.

I will also ask again:
>> Your thesis.... How is it that you EVER expected a first iteration
>> Sierpinski to be a suitable candidate? Why were you so specific to
>> the first iteration? By all of my research, the Sierpinski is the
>> most mundane design around, hardly matching the radical requirements
>> that devil you above. Simple research reveals that higher order
>> iterations yield more resonances, just what you demand; and yet you
>> limit yourself to one iteration from the beginning.
>
You have to come to terms with the obvious force-fit of a solution to
a problem. Your observation:
>From literature is known that a dual-band Sierpinski monopole antenna
>exist but it seems that the behavior of a Sierpinski on a patch
>structure is different..
reveals no data to support your thesis. It is gossip at this point
without knowing just what those two bands were. I would suggest that
you stand back and look at your frequency requirements and appreciate
they are very close to one another. Yes at that band it may be many
MHz apart, but as a function of proportion, it is a razor's edge
between them. No first iteration Sierpinski on god's green earth is
ever going to do it.

Try for a higher iteration Koch Quadratic if you want more resonances
in a smaller package. I suggest this only if you wish to maintain the
fractal purity of your thesis - but mind you, optimization (if you

need it, and you probably will) is bound to destroy that fractal myth. If you followed this group a little more, you may have noted one of the "major" proponents of commercial fractal development is abandoning fractal purity with a vengeance (optimization a la genetic algorithms). The joke of these optimizations is that an hour's worth of doodling has eclipsed their best product every time.

If you are forced to maintain a triangular outside dimension, simply distort the cartesian co-orinate system of the Koch Quadratic to fit.

Yes, I did finally find one, and bought it. I got an email from a local Fresno ham who had the 80/40 meter version (MPD-2, 85') for sale brand new still in the shipping box. I bought it for $50, and it's great.

It's entirely flat across the 40M phone band, and with a tuner it works great on 80M. Without a tuner, SWR rises to about 2.5:1. I have an Alpha 99, and as a test pumped the legal limit+ into, and no sweat. W9INN's are good antennas.

1790. How to suppress indoor RFI ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-26 23:58:37 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0207261558.1c667bca@posting.google.com>
Source record: 137931

Hi,

As many hams/swl I quickly discovered that portable PC or desktop computers located near the RX/TX produced a lot of QRN : from the screen - few -, the power supply - much -, or even from the move of the mouse or from the color displayed of the screen - sometimes-. A battery charger (for a digital cam) located 2m away from the RTX, on the ground near the power line, is even the strongest emitter and I must switch it off without condition when I listen to HF bands.

But from time to time even when the PC is on, I heard stations without switching on the N.R.1 and Beat cancel filters on my TS-570D. This is amazing but true as usually I can only heard the strongest stations without these filters. Suddenly like by miracle it seems the bands and all RFI are silents, without generating QRM/QRN.

On the contrary sometimes, my PC seems to generate much more QRN than usually and I have to switch it off to hear HF bands or weak remote stations. Sometimes RFI are even generated in the middle of HF bands, for example at 21220 Khz or 18160 Khz, but that changes regularly, without structure at first sight.

FYI, my PCs are located very near my RTX (see pics on http://wwww.astrosurf.com/lombry/qsl.hm and http://wwww.astrosurf.com/lombry/qsl4.hm).

On the pictures of shacks I have seen, - like to yours probably - the PC stands often very near the RTX due to the fact most of us use the PC to record our QSO or to access simultaneously to Internet. So I cannot place my PC far from the RTX. It must be on the same table, even if the main unit is located about 1 or 2m away from the RTX. My coax is not more far away.

Question : What is in theory the solution to suppress these RFI ?
Is there a solution to remove (or filter) this QRN generated by PCs or electronic homes devices in order to heard HF bands without these RFI (and keeping the PC near the RTX of course) ?
Can an external DSP be the ultime solution in such a case ?

Thanks for comments

Thierry:

First, let me help a little on terminology. QRN implies natural sources, like lightning and other atmospherics. QRM doesn't fit well, but is the closest Q signal. What you are describing is indeed RFI or EMI. No Q signal for that.

Now, try a little test. Put a shielded 50 ohm termination on the RX/TX antenna connector. If the noise is still present, then you are going to have to work on shielding of the RX. If it is clean, next try with the termination at the far end of the feedline. If that picks up the interference, relocate the coax, or use double shielded coax. If that is clean, then it is getting into the antenna, which is the correct route for signals and interference. Filters on the computer cable connections, all cables shielded, and perhaps some additional shielding around the PC power supply and monitor power supply will be required. Antenna tuner? Be sure it is properly shielded, as many are not. Too many slots in the case. My PC and computers are adjacent, and I have no interference, but the antennas are a minimum of 30 meters away, and I use only double shielded coax or hard line.

Robert Rose wrote:
"If 30 MHz to 2 GHz is too wide a spread, would certainly be willing to consider 2 antennas,---."

Depends on how critical the application is. A shortwave broadcaster changes frequency by 50% and he usually changes antennas for something more suited to the new frequency. Generally, this means the broadcaster changes antennas every time he changes bands. The cost of listeners makes this a good trade-off.

A single TV antenna may serve a user from 54 MHz to nearly 800 MHz. The antenna is likely to be more a conglomeration of antennas connected to a single feedline or two. As Richard Clark noted, uniform performance shouldn`t be expected over such a range.

Then , there is a telescoping vertical over a large conducting sheet which is length adjusted for each frequency used. Regardless of elevation, performance of this antenna is a function of wavelength and how the atmosphere treats the signal over this wide frequency range.

Best regards, Richard Harrison, KB5WZI

You make my point so clearly. You have dismissed the antenna outright
without looking for possible advantages and do a diservice to ham
radio without giving it a shot PROBABLY because it is not in an arrl
ANTENNA BOOK , AND YOU ARE SO...SO WRONG. I have used this antenna for
years and I know it works and want to share it with all. I also want
to share with new amateurs that experimenting with fishing poles with
a conductive surface is so much cheaper than buying telescopic tubing
unfortunately these things are passed by unless utterred by a 'known'
person or it is a book. I would love to hear from a novice ham who has
spread his wings by making a log periodic using poles with an aluminum
surface
instead of that shown in the antenna book made of wire and string to
achieve lightness.
So do yourself a favour, try it a use a computor program to check
it out or maybe Reg will modify his 'loop' programs to prove my point
so we can review the overall subject of 'stagnating antenna designs'
rather than presenting a 'off the cuff' notion without thinking it
out. If it does not have merit you have the option of saying 'I told
you so' or conversely you can rate the merit of the antenna
advantages/disadvantages to the enjoyment of all.
Nothing personal intended, but please note that no one has stated so
far that it is without merit , because it is not yet 'written in the

book'.
Have a great week end
Art

Hi Sean
I took a 1.5 " pvc and put a 19"vert up and then hooked a coiled 20" to the panel mount 239 for the ground and it worked great! You have to stretch the coil around to adjust the swr but the it works pretty good as a portable and as a ventenna type hidden antenna.Email me direct if you'd like more info

Art Unwin wrote:
"With respect to feeding I show a delta match----."

Art seema to have a definite antenna in mind, but he raised a question of why innovation seems automatically rejected on arrival.

People are invested in the status quo. That`s why they reject innovation.

Why isn`t more written about connecting to antennas of opportunity? Too hard to predict results and who would profit from this activity? Maybe the practitioner and a tuner maker or two.

Best regards, Richard Harrison, KB5WZI

Going back to my initial post where I compare to a zepp which is
usually made for a fixed frequency, it would hardly be fair to compare
with a design that has a VARIABLE capacitor. There is no snake oil
involved here.
>
> >So what does the above give you?
Actualy it doesnt, iyt takes the place of the transmition line stub
and the center portion of a dipole which contributes to those side
lobes on the zepp patten where the radiation created to form a
collinear does not fully cancel.
To make this capacitor variable suggests to me that multiple feed
lines to
obtain multi frequency use for a zep could be replaced. Merit, that is
for the experts to decide.
>
> A large, variable gamma match; so large that it contributes to the
> radiation if I follow your description.
Well I do not see where the large gamma match which is variable comes
about
but yes a gamma match radiates but also supplies an impedance that can
easily be
matched. Again merit is in the eye of the beholder.
>

> "modestly superior."

All dipoles made for a particular band has quite a variation with
respect to gain with a high gain only met at a particular frequency,
nobody high lights the low gain at the end of the bands but to the
amateur this is very interested.
Again it is the eye of the beholder. The trapped antenna does not
radiate along the whole length of the antenna so the gain loss is
heavy where the combination
antenna radiates from each end of the antenna and provides the added
gains for a collinear. Superior ? Try it out and compare the numbers
and see if anything of interest show up.
You also mentioned the complexity of turning the capacitor and I
suppose that is a huge demerit in some eyes but it is really as simple
as it gets and accepted for the loop, so it is not so complex to stop
people using a loop antenna despite the difficulties encountered with
that particular antenna
So Richard, knowing you have considerable expertise with the computor
and antennas please do me the honour of checking the figures so the
response will be factual and informative to all.
Hang in there buddy, sometimes I ask at the dinner table where the
salt is
and all hasten to point out that it is right in front of my eyes, but
yet I did not see it.

Geometry of the return conductor is significant at VHF. The length of the resistor is about 20cm, iirc. That's 1/10 wavelength at 2M, which is enough to create considerable reactance.

Some loads have a tapered cylinder for the return conductor, with the spacing set for 50 ohm characteristic impedance at the coax connector, tapering down to no spacing (0 ohms) at the ground end of the resistor. The ideal case is that at every point along the coaxial structure of resistor and return conductor, the characteristic impedance is equal to the remaining resistance from that point to the ground end of the resistor. This absorbs the return lead into a lossy coaxial line, for good SWR at VHF and even UHF (if the construction is good enough).

Art, I understand your fondness for the antenna you've created -- you've mentioned it quite a few times before on this newsgroup. I encourage you and others to take a look at the ARRL Antenna Compendium. Last I checked, six volumes of this have been published. They're chock full of innovative antenna designs. Some are particularly good at solving some problem or another, but nearly all do so at the expense of something else -- efficiency, mechanical complexity, gain or directivity (too much or too little), and so forth. I hate to tell you, but your antenna, much as you may like it for your particular situation, is no exception. I can build a trap dipole to operate on several bands, feed it with 50 ohm line, and forget it. I can hang it from two supports, or put it up as an inverted vee from one support. I can build the traps from a few pieces of PVC pipe and some coax. No tuning, manual or automatic, is required. That doesn't make it better than your antenna. But it certainly has some advantages for a lot of users. I personally prefer it for my uses, over finding a high voltage variable capacitor of adequate range, weatherproofing it, and providing a means of remote tuning. Each to his own. You can take any two antennas and write a list of advantages and disadvantages, and seldom will one come out on top in all regards for all users.

The place for new and innovative antennas is publications like the Antenna Compendium, or books like Moxon's _HF Antennas For All Locations_. The ARRL Handbook and Antenna Book are the appropriate places for antennas that many people have found to be useful and advantageous and are using as a result. Out of all the antennas in all the textbooks, in all the Antenna Compendium volumes, QST, RadCom, CQ, ComQ, Ham Radio articles over the years, in books like Moxon's, is your antenna really so wonderful that it should merit inclusion in the ARRL Hanbook among the very few that can be included? Is it really so much better than the thousands of other innovative designs?

Here's how to find out. Write it up and submit it to the ARRL for publication in the Antenna Compendium. If you have a problem with that, choose any other magazine of your choice. Or post it on your web page and tell your friends about it. Then wait and let the test of time determine whether yours is really so great as to attract a following large enough to put it in a class with tried and popular antennas. Or whether it'll join the thousands of other designs that are great for some and not so great for others.

You seem to feel that your antenna isn't being recognized by the world because the ARRL doesn't include it in their Handbook. But I think you have it backward -- the ARRL doesn't include it in the Handbook because not enough people have adopted it to separate it from the vast hordes of

innovative antennas vying for attention. It's up to you, not the ARRL, to convince people that it's the greatest thing since canned beer. Only then will they grab their openers and join your party.

Roy Lewallen, W7EL

Chip,
I believe that I have made my point already. Comments so far have
been 'off the cuff' responses that would discourage any new ham. The
task at hand now is to persuade the knoweledgable to go beyond that
and take a few minuites with AO
or some of Roy's programs or even place dipole extensions on a loop
antenna which they may have at hand. When one of the more knowlegable
finally succumbs and does a modicom of leg work for himself rather
than leaning on hunches or looking up 'the book' will the true meaning
of my original post become apparent regarding 'stagnation.' All I am
pointing out is that we all tend to dismiss the new or different as we
get older, focussing on hunches or the absence of articles to take the
time to verify for oneself. In this particular case I have made some
sweeping statements and asked for verication based on merit BOTH the
good and the bad which on this forum is like pulling teeth but ONLY
when completed will I have met with success regarding the original
post on
'antenna stagnation' be fully understood.

(The Airport Base Station is a 2.4 GHz system that can be quickly attached
to any recent Mac computer; it's very popular for use in conjunction with
current Mac portables, which have relatively inefficient internal antennas
already present whether ordered from the factory with an Airport card or
not. Airport is compatible with most of the other currently available
"WiFi" systems.)

There were a number of replies, some of them suggesting improved antennas
for use with 2.4 GHz wireless connections, and other suggesting buried
coax. Here's what I wrote in article
<ryeburn-2507022229540001@207.6.87.119>:

What thoughts do you have on this? Has anyone tried burying CAT5 cable, using PVC pipe as I suggested? What types of coax are available which will tolerate burial without protection, are of relatively small diameter, and aren't too expensive? I've read enough in this group (rraa) about the ease of burying radials by just making a slit in the ground that I don't think building a big trench is needed, as long as the coax, or the PVC pipe, is of fairly small diameter.

Just as a distantly related data point, we've had a Cat 5 cable slung
for maybe 100 feet across the flat tar & gravel roof of a house in SF
Bay Area for a couple of years --bakes in direct sun all summer, rained
on all winter -- and had no problems.

I'd suspect that if you buried an unbroken run of good quality Cat 5
cable with a good quality jacket in a slit trench, inside a half inch
plastic conduit for mechanical protection, not necessarily watertight
but with the ends of the cable brought up above ground level and into a
structure at each end, you'd have no problems -- but that's only a guess.

You CAN buy direct-burial CAT5 cable. Also, a sealed conduit will help keep the cable safe. I'd do both myself ... for just in case the conduit leaked.

Also, you can buy direct burial RG-58A/U (well, RG-58, anyway!) but that will force you to 10Mbit data. Might not be a problem if you're comparing to the 11MBit max of Airport, but still ...)

>
> David, ex W8EZE

You probably know more sources than I do - but a quick Google does turn in a lot of sources for CAT5 direct burial cable.

> David, ex W8EZE

You have to use RG-58 for coax - it is typically about the same diameter
as RG-59? 62? CATV cable. I'm sure it is available in weather-resistant
jacketing, and if you keep the termination points indoors it would
probably be quite durable even in a wet conduit. If I were actually
doing this - which I probably wouldn't, see my recommendation on
wireless - I'd see if multimode fiber fit the bill. It is resistant to
all but physical damage, can support a number of popular network types
from FX100 Ethernet (very cheap) to GigE and faster/future technologies,
and avoids the grounding headaches of copper. Downside is media cost.
(Obviously coax can support massive broadband transports, too, but
practically none of them are packaged for the consumer.)

If you use copper, grounding is a problem. Two separate buildings very often have different ground potientials. 10Base2 needs to be grounded at exactly one end of the bus. 10BaseT doesn't really have provision for grounding other than at the hub/switch. In either case, you also have electrical/safety/code issues to deal with as well as just the signaling.

How much loss does the oxide layer that forms on the
wire cause?

If you use galvanised wire for the antenna, the
losses rise substantially as the zinc is eaten away.

The discone has always been a beast mechanically due to it's number of
elements and the angles involved in the hub.

The Radio Snack antenna is a great electrical implementation but like
Hasan says, it vibrates apart in a steady breeze. I fixed the problem
by using LockTite on the outer quarter of the threads on each element.
You would not want to LockTite the entire thread since this could
possible electrically isolate (insulate) the element from the hub. I
tossed the little lock nuts that are on the elements and only rely on
the LockTite. I have two at our camp up in Canada and they have
survived three Northern winters so far without problem.

Source record: 137952

I bought a Yaesu G-1000SDX rotor a few years ago and am now just putting it up. The control cable connects to the rotor with a 7-pin round connector but only uses 6 pins. The instruction manual say ""pin 6, the center pin, is not used". However, the center pin is pin 4, not 6.

Does anyone know for sure which pin is not used? Is it the center pin (4) or pin 6?

Thanks + 73, Charlie K0CKH

If the RS discone was made with solid elements instead of the hollow
ones that are crimped onto the threaded part, it would be a much
better antenna. I just got through soldering up all my elements because
they were loose to the point of falling off. I sure hope this "fixes" it!

Art, Art, Art, calm down and steady yourself.

It may be that your design has merit, but in reading all of the prior posts I'll be damned if I can figure out exactly what you're talking about. You are going to have to publish something understandable on a web site or on paper with some readable illustrations and analysis before you can legitimately claim that you are being ignored.

I'm as eager as anyone to challenge the conventional wisdom of some "prior art" as you might conclude by reading my thoughts on the "advantages" of ladderline and "G5RV" antennas. I might be all wet with my conclusions, but I put 'em out there for discussion, in what I hope is understandable form.

I know that Dean Straw, editor of the Antenna Compendiums and the Antenna Handbook, is begging for something fresh to publish. So if you are unhappy about the "tired old, worn out designs" that are regurgitated annually, do something about it. Write it up and send it in.

Have you heard of Robert's Law?

It says:

Any antenna you wish to use is always 10 feet longer than your lot. The correlation is, if it fits your lot, the SWR is too high.

The frame isn't much in the way of a groundplane, and based on the stuff I once did with a 1959 Cushman Eagle Scooter, I'd say the ground losses will be about 20 ohms on 40 meters. The tuner should handle that ok, but your efficiency will be very low, say 2 or 3% on 40.

QRN = Natural noise, i.e. power line QRN, automobile ignition QRN.

QRM= Man Made interference....ie. noise from another transmitter nearby.

PC = QRM...certainly man made and most certainly noise from another transmitter.

How does one cure that crap? Physically seperate the units.

Seperate the RX antenna from the PC as much as possible.

Use shielded cable on EVERYTHING.

Dan/W4NTI

According to my manual, the round connector has 6 pins and the center
pin is marked 6 and not used. The rectangular connector at the control
end also has 6 pins and again only 5 are used. I suggest going by the
picture in the manual and not any markings on the connector itself.
Different manufacturers of connectors do not always number the pins the
same way.

Which should work better for 160 m? A 80 m dipole cut for
3750 or a 40 m dipole cut for 7150?

Which would work better for 10 m?

Both are fed with RG-213.

I heard one can disconnect the shield on the 80 m dipole and
have it work better on 160 m??

Richard,
I may have misread your post
but I do not have any monetary interest in this style of antenna or
any others
I withdrew from the patent scene some years ago and withdrew from
amateur radio for a while. If somebody picks up the torch and gives a
'how to' post on how to utelise a 'stamp' to automate it I could not
be happier. If they make some money while pursuing the idea then good
luck to them. My post is to strictly make a point about 'stagnation'
and what creates it. The basic idea IS in old antenna books where a
ham shows a instrument or antenna formed in a figure '8' to show how
one can desensitise structures or poles that may be affecting other
wire antennas . It is not a new basic idea nor is the use of 14 foot
fishing blanks
or driving existing verticle structures to make a variable frequency
antennas
or its use as a dipole with a full frequency sweep or infact any
antenna that presently uses a stub where replacement uprates the
frequency sweep. Yours is the last post that appeares on my computor
but at the end of the day I am hoping that one expert will not dismiss
it with hunches and give it some validity
if my posts have merit.
P.S. Were you the person I sent a picture to where I showed a 80 foot
plus long antenna with 13 elements made of fibre glass poles ? I have
not been well for a while and I have slightly lost track of things

As I told the last guy looking for one, if you are going to use it for its intended purpose:

Get a copy of ANSI C2 National Electric Safety Code (note this is not the NEC),
Always have it hi-potted before use,
Use it only with certified high voltage gloves,
Make sure your insurance and will are all in order.
Also be sure your high voltage certification is up to date, I think OSHA only recognizes it for 5 years now.

If you are going to cut it up for antenna poles, there are a lot less expensive alternatives.

>involved here.

Hi Art,

Going back to your initial post has nothing to do with multiband
requirements driving the necessity of a variable capacitor for the
design you offer and the specifications you claim.

Further, if you want to champion an antenna, it is very poor form to
choose poor examples to compare it in contest. Skip the discussion of
the Zepp altogether, unless you are more interested in its exclusion
from the canon of antennas than you are in your own's inclusion.

>>
>> >So what does the above give you?
>Actualy it doesnt,

Art, do you realize how hard it is to follow your logic when you
directly contradict yourself? The two lines above were both authored
by you.

>> A large, variable gamma match; so large that it contributes to the
>> radiation if I follow your description.
>Well I do not see where the large gamma match which is variable comes
>about
>but yes a gamma match radiates but also supplies an impedance that can
>easily be
>matched. Again merit is in the eye of the beholder.

Who is talking about merit here? Show me more than a dB before we get
into the emotional specification.

>The trapped antenna does not
>radiate along the whole length of the antenna so the gain loss is

>heavy where the combination
>antenna radiates from each end of the antenna and provides the added
>gains for a collinear. Superior ? Try it out and compare the numbers
>and see if anything of interest show up.

Art, I have been doing that for quite a few years now. I have seen many interesting things - and to the surprise, perhaps, of some, they were fractals.

Surprise, Interest. Each of these emotions absolutely did not translate into the pinnacle of performance. For myself, surprise and interest led me to literally thousands of failures (most of them available for viewing at my pages). But amongst those thousand abominations I found that I had gained in insight through the investigation of them.

>So Richard, knowing you have considerable expertise with the computor
>and antennas please do me the honour of checking the figures so the

>and all hasten to point out that it is right in front of my eyes, but
>yet I did not see it.
>Regards
>Art

Art, it is your responsibility to provide an exact model to us, not for me to rummage around with equivalents. This is a minimum requirement to enter the canon of antenna.

Hi Thierry,

The other's discussion is to the point and fairly simple to achieve.
There is something even easier to try and will be the probable

solution.

Connect the laptop power supply to an outlet on a separate circuit breaker. Use an extension cord as necessary (do not move the laptop). Whatever noise reduction you gain, that noise arrived by conduction (common wiring).

Second, investigate your equipment grounding (common wiring again).

The longer the antenna (closest to a half wave or more) the better signal you'll put out. Height is a plus. As an option you may want to tie the shield and center conductor together and run it as an end fed zep. Any configuration you use will require the use of a tuner since it won't be resonant anywhere on 160M.

If I were to do it I would use a router hub and use 3/4" plastic pvc schedule 40 pvc conduit and the best CAT5 plenum or direct burial cable I could afford. Distance, by the way, between a machine and a hub is on the order of 100 meters or so it says in my D-Link DFE-530TX+ manual. I love these nics. Others will hate them. Since the CAT5 is twisted pair some might argue that 1 inch conduit would allow for the cable (likely RG6/u) and the CAT5 to be in the same tube.

Also there is another thought for the conduit. How about 1" semi rigid plastic pipe that is used for well to house connections. Unless you are in a heavy ground frost area with gravel for soil it should last for years even though it isn't buried feet below the surface. It saves on the time gluing each joint etc though feeding the wire through may be tougher.

I vote for optical fiber, too. From the Linksys line, you could get two 16-port switches with fiber uplink modules for about $600, and ST type (multimode) duplex fiber seems to run about $0.50 a foot in bulk. Good for 2,000 meters, they say. Burial & lightning protection should be easy.

Has anyone tried this in ham applications?

1839. How much signal is going out?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-28 01:21:42 UTC
From: cprstn54zz@att.net
Message-ID: <3d4346fc.245562000@news-server.optonline.net>
Source record: 137880

If my SWR/wattmeter shows 100 watts forward and nothing reflected (SWR=1.0), does this mean I am pumping out a 100 watt signal?

I am finding that my MFJ-986 can tune my multi-band (160-80-40-20-10) shortened dipole to any HF frequency at SWR=1.0 -- even some improbable frequencies not mentioned by the antenna manufacturer, like 30M, 17M and 12M. Does this necessarily mean I am getting out a good signal?

Ken,
It means that the antenna is probably radiating
everything that's being sent to it. That doesn't
necessarily mean you have a good signal. That 1:1
SWR is between the radio and the tuner, the SWR of
the antenna system (feed line and antenna) hasn't
been changed.

Stargazer,
Not enough information. Depends on how high each
is off the ground. Also, if you disconnect the shield
from the SO-239, then short it to the center conductor,
you might be able to use either antenna on 160 meters
if you use a tuner. Still depends on how high the two
antennas are...

If this is a problem, it might be easier to use fiber.

Multimode fiber isn't terribly expensive, and you can get tranceivers to convert between 100BaseT and 100BaseF. The tranceivers can be a bit pricey to buy new, but I've seen them sold really cheap at computer flea markets (collected from dumpster diving at defunct dot-coms, probably).

The ammount of swr has no real meaning on how much signal is getting out. By using a tuner all you do is allow the transmitter to put its maximum power into the antenna system. You will loose some power in the tuner. Mine looses about 5% depending on the band . Even with no tuner (provided the transmitter will put out the same power) you can have a dipole with a very high swr using open wire line and radiate a beter signal than one fed with coax and a low swr.

Your definitions are at odds with what I think are the original meanings.

QRN - I am being troubled by static
QRM - I am being interfered with

Further, neither power line noise or automobile ignition noise are any
more "natural" than computer generated noise.

It means that your are putting 100 watts into the feedline - nothing more.

For example, assume you have an infinite length of coax with no termination (or shorted, it doesn't matter). Because of the attenuation of the coax, no power would be radiated and none would be reflected. So the VSWR reading would be 1:1.

As a more practical example, assume that your coax has an attenuation of 3.33 dB per 100 feet - and that the coax is 300 feet long. If you feed 100 watts into the coax, only 10 watts is getting as far as the antenna. Even if the coax were shorted, so all the signal were reflected, only one watt of that 10 watts would get back to the VSWR meter at the rig. That 1 watt would only slightly deflect the needle on your meter.

Oh, I have no problems with such foil methods. Whatever works...The
only thing with foil is trying to get good connections. And then keep
them with the effects of wx. Can't solder to it too well. I have done
things like make vhf yagis from coathanger wire...

That would be no problem to model. Or at least I don't think it would
be...
I'm willing to give it a shot. But my comments were not without
thought.
I still am not sure how you are going to couple power to a radiator
that shows a high impedance to the feedline when you have the loop
tuned and showing a fairly low impedance. IE: 50 ohm coax feeding a
small tunable loop parallel with a 1/2 wave dipole at a certain freq.
Lets say the dipole is cut for 40m. Now go to 20m, and tune the loop
for 20m use. Seems to me if it shows a low impedance to the line, and
the dipole show a high impedance, such as a full wavelength would, the
loop would accept the majority of the power. And being the loop would

not be too efficient, I don't really see how the performance on 20m, would equal or exceed the performance on 40m, where it would naturally be good being the dipole is resonant. If I'm missing something here, maybe someone will jump in... Am I describing the antenna correctly?
MK

> have it work better on 160 m??

Yep, thats the best plan. Feed the 80m antenna as a T vertical. If you are lucky and have the right distance to the antenna, you can tune it for 160m by varying the length of the coax to make a 1/4 wave total length. The 80m antenna is better because it has more top loading . Lets say you have a 120 ft dipole cut for about 3.850 or so. Each leg is 60 ft. If you tie the shield to the center pin, or, just feed the shield alone, you can add about 66 ft or so of coax to make a T vertical for 160m. Naturally, the coax would need to be supported above the ground for best results. The only problem with this plan is you are feeding directly from the shack, and should have grounding and radials for best use. But it will work even with less than best ground systems. Amounts to a shack fed inverted L, if you feed only one conductor. Would probably have a bit more high angle use than the T vertical, which is what you have if you tie the coax together. The T might be a bit better for longer haul stuff. I don't know which would work better for 10m. Probably the 40m antenna. MK

O.K. Wes if my computor works o.k this morning listen to my story.
My training is that of a engineer with G.E but after 25 years I had to
retire because of heart attack, many depression periods, sleep apnia
e.t.c so I can understand that my writing is not all it should be.
Many years ago Moxon showed this antenna in the British Radcom,
unfortunatly he did not go far enough with it plus he called it the
case of the disapearing induntance. Progress that stopped him was an
everyday thing for me and I made these antennas plus a lot more. Later
it was published in his book, I forget the name now but still it
didnot attract attention. After talking with him at his home about the

variable cylinder type of capacitors within booms e.t.c. I asked a friend of mine to show my stuff to the British ham assoc where they viewed it with some suspision.
I took out a patent in fact a series of patents some of which I abandoned with discust before the examination period because I recieved similar comments from this group as I am getting now and at that time I had also placed on the net a page showing construction methods.
Since it got no follow up interest I got the AO program and worked with it. Unfortunately in those early days I made many mistaks using the program that I began to doubt myself. Eventually I amnaged to get the University of Illinois to do a study on the sly (they were working on fractals at that time, and they confirmed my work. I then gave a couple of lectures at the Peoria ham fest which that year was the premier hamfest of the ARRL for that year. Prior to giving those lectures I sent the material to Dean Straw you was nice enough to give me some tips on presenting it.This post is getting too long so I will finish.
But for those who are willing to join the rest of the lemmings in following the crowd start thinking back to first principles and consider what you get when you add two frequencies as a tip for how this antenna works. It only takes ten lines of info for a AO style conformation of what I am claiming and I am willing to work with anybody who is willing to give me a modicom of repect and bear with my obvious difficulty of explaining things with my present problems.
Best regards to all
Art UNwin

This in-line, end-fed, unidirectional, array works well with
1/4-wavelength spacing between masts. Such an array is shown by Terman
in his 1955 edition of "Electronic and Radio Engineering" on page 878.

All elements are fed equal currents, progressively delayed by 90-degrees
so that energy arriving from coax and space are in-phase in the desired
direction.

My father-in-law Phil Rand, W1DBM, built an 8-element, 20m array on his
New Hampshire farm, which he demonstrated for me, Like "Hello
Australia", and the responses boomed in, and he did this almost every
day. That array shook the aether with its power. It was written up in
some ARRL publication, as I remember. This was about 20 years ago or so.
The coax power division and phasing arrangements were simple and clever
as I recall.

Best regards, Richard Harrison, KB5WZI

Correct. I discovered that also but it is not enough.
I think shielded power lines will be the best solution. I will try to
find that (I even didn't know that such cable existed for private
usage...).

But the problem stays for my DELL portable that - like all portable and many small devices - uses a specific cable between the PC and the AC adapter (with a proprietary 3 inputs jack). I could probably not shield that one. For the wall outlet this is OK i hope i could find shielded power lines.

Thanks.

There has been a lot of discussion in this NG about choke baluns over time. It seems to me that the simplest, cleanest & easiest way to attenuate common mode currents on coax cable shields is a stack of ferrite beads along the cable at the feedpoint of the antenna or tuner. The question in my mind is "how many beads are enough?" particularly at HF frequencies which are the focus for some experimental antennas I plan to get into. Is there any sort of engineered standard and/or common practice in terms of dB worth of attenuation required to construct a proper choke? Or is it all just more ham black art and mythology?

I don't know what Martin was referring to, but I visited Black Box's web page to look up their prices. Black Box isn't the cheapest, but they're a well-established company with a good reputation. They will sell termiated cables at custom lengths:

http://catalog.blackbox.com/BlackBox/templates/blackbox/itemgroup478guest.asp?param=90&ig_id=478&title=Ceramic+Terminated+Multimode+Fiber+Optic+Cables&related=

Their lowest price for a terminated multimode cable (duplex, riser, with ceramic SC connectors) is $58 plis $0.70 per foot.

Of course, other products and other vendors will have other prices.
This definitely isn't the best. It's just the first that came to mind.

Hello:

Am looking for a not too expensive VHF/UHF for installation in my attic.

Receiving only.
Have an old Antenna Specialis MONR 31 which I've never thought too much of.

A lot of people have mentioned Discones.

Would this be a good choice for an omni directional 30 MHz to say 1.5 GHz ?

Caveats ?
Negatives on ?

Thanks,
Bob

Actually, the flue pipe is pretty large diameter, and that lowers the resonance considerably. The model Ken provided me shows resonance at 4.6MHz.

Your decoupling wire idea works fine for a bottom-excited antenna, but unfortunately it appears the way this is being excited (by the antenna above and around it) it doesn't do much good (per EZNEC model). I'm kinda surprised how much current the model shows in the flue pipe, but it seems to match Ken's experience.

Cheers,
Tom

Hi Crazy,

You've touched the edge of internet2. This is principally a
university based network researching high speed high capacity
connections. Typical customer/client connection runs at T100 (my
cable modem runs about T1 or better) moving one teraByte of data.

Here in Rain City there is a "branch" that runs from the University of
Washington to the Microsoft Campus with a T1000 capacity.

I would also point out that the United States currently has a 50 fold
over capacity resource in fiber-optics. What we called the
information superhighway is a rambling rutted dirt path.

Hi Thierry,

Shielded power lines seems rather severe and does not answer the
source of the noise. It is unlikely that ALL of your computer devices
are noisy beyond EU standards, so it must be a common problem (that
is, your radio equipment and computer equipment SHARE something).

By the way, how well does your computer do running off battery?

Hi Brian,

The question of how many is relative to need or intended use.

However, as you have identified experimentation; this means one answer will not work. I have several engineering samples kits for ferrite products and they span quite a few formulations and form factors. I have measured and confirmed their manufacturer's specifications and calibrated the individual pieces.

If I were to take a sample at random with the standard bead dimension, I would treat it like a 20 Ohm 1 W resistor. If your transmission line had the prospects of acting like a quarterwave antenna and you wanted to choke that 32 Ohm load- One bead probably wouldn't do very well, and certainly not in the face of 100W transmission levels.

A Technician's rule of thumb would be to present at least three times the load's impedance to that load - about 5 beads. The Engineer's rule of thumb would be five times the load - about 8 beads. The Metrologist's rule of thumb would be ten times the load - about 16 beads.

Now, as to the mystical elements. As only you will be aware of the conditions that are to be choked, you will have to shop for the ferrite formulation that is optimized for your frequencie(s) of operation. Amidon sales material is quite informative to this.

1866. Shielded parallel feedlines

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-28 19:41:13 UTC
From: Chris Codella <codella@frontiernet.net>
Message-ID: <uk8i8276aphhbf@corp.supernews.com>
Source record: 137908

I would like to replace the coax that feeds my 80m dipole with a balanced feedline so I can use it with a tuner on other bands efficiently. But open-wire and other balanced lines need special consideration going through walls, near objects, etc. Also, my other antennas are fed with buried coax, mostly for appearance sake. You can't bury open wire.

I was reading the 2000 ARRL Antenna Book and came across a part in the chapter on transmission lines (24) which talks about using two parallel lengths of coax as a balanced feeline that is shielded and thus can be used near metal, go through walls, can even be buried (see page 24-20). You connect the shields together at both ends and feed the two center conductors as a balanced line. Granted, it's an expensive way to feed a dipole but it seems to make perfect sense if you want to simplify and hide the routing of the feedline.

By the way, I imagine that a parallel coax feedline is distinctly different from shielded twinlead (or similar) where both feedline conductors are within a the same shield.

Has anyone here tried this? How well did it work?

73,
Chris, W2PA

>The question of how many is relative to need or intended use.<

Not really. Generally, I try to raise the blocking impedance of the line as high as practicable in order to cover the widest possible range of circumstances. It isn't that "black magic" is afoot, it's just that the load presented by the outer cable shield is notorious for being difficult to predict.

Although I stack beads for convenience, stacking isn't the most efficient way to make a feed-line choke. Winding coax onto a large core of the appropriate mix (or even air-winding your choke) takes a lot less ferrite material in weight. Many of the better cables in the RG-58 family (RG-303 etc) can handle plenty of power in the HF region without breaking down, so you really don't need to stack cores on RG-213 to make a 1-kW balun.

Here are some other things to think about. As you stack on more cores, the choke's Q at Z-max increases (reducing effective bandwidth). Also, the frequency of Z-max tends to migrate downward. As a result, if your choke uses a lot of beads to ensure optimum performance on 75 and 160 meters, it may not be very effective at all on the higher bands.

Finally, these ferro-ceramic materials introduce both a resistive and reactive blocking component to the line they are choking---and the ratio of the two rarely remain constant for changes in mix permeability or operating frequency. To avoid heating problems at high power, it might be better to use a larger cross-section of a lower-permeability mix to prevent resistive (destructive) heating in the material.

Having said all that, I generally use 43 mix beads above 10 MHz and 77 (or 73) below. Haven't burned up my coax so far by doing that.

Source record: 137910

A rule of thumb that seems to work in practice for nominally 50 ohm systems is to create a balun impedance of 500 - 1000 ohms. To determine how much impedance an individual bead has, you either have to measure it with an impednce meter, or look at information provided by the vendor. A lot of the more popular and suitable beads are Fair-rite type 43, and you can get information about their impedances at the frequencies of interest at the Fair-rite web site. The total impedance is simply the impedance of a single bead multiplied by the number of beads. (This is why I prefer to use multiple turns on a single core -- the impedance is proportional to the square of the number of turns.)

20 ohms seems a little low and is by no means purely resistive. It much depends on bead dimensions, especially length. Actual values can be measured on an antenna analyser using the Z or R+jX range.

It should be made quite clear the impedance of N beads is N times the impedance of one bead.

The impedance of 1 bead can be increased by passing the conductor through the hole-in-the-middle twice if mechanically possible. Z then quadruples.

If you feel like passing the conductor through a lot of times then use a big bead with a big hole in the middle. This is known as a torroidal winding. It is much lighter in weight for the same impedance and a much less expensive way of using ferrites.

And beads and torroids need not be touching each other. Indeed there may be advantages in spreading them out along a length of coax to break up resonances.

Efficiency won't increase much. The lower loss in balanced line is due to
the higher impedance; something you really won't gain with parallel coax.

There's no problem bringing open-wire lines through window frames and walls.
Just bring the two wires close together through a relatively small hole with
some extra insulation round each wire and around the pair. 3/4" or 1"
diameter holes are ample. In brick, timber or metalwork.

The transmitter thinks there's an extra 2 or 3 pF across the line or the
line has increased in length by 2 or 3 inches. There's no extra loss.

NEVER bring openwire lines through TWO holes unless the material is a good
insulator such as a glass window pane or a really dry wood panel.

Chris,

I use this method for bringing my parallel transmission line through
the wall and into the shack. However, I am only using about four feet
run of the parallel coax. It works fine.

For what you describe I would use only the coax for those portions
which that are buried and/or going through the walls and use the open
line for the rest of the run because the coax losses will be
considerably higher than the open line. There is no requirement that
in a tuned feeder application that the transmission line's impedance
be constant - the only requirement is to keep it balanced - so mixing
say 100-Ohm and 400-Ohm lines will be okay.

Can someone with an MFJ schematic or 2 minutes to look at their MFJ-249 or 259 give me the value of R-31, the potentiometer that is part of the calibration procedure for the MFJ-249 antenna analyzer? It is the middle of three pots located below IC1.

Opening your MFJ-249 and looking at the circuit board with the tune capacitor at BOTTOM RIGHT, IC1 is about 20% down from the top on the right side of the board. The pot to the left of IC1 is R-17, the SWR adjustment. The pot in the
middle of the 3 below IC1 is R-31, the resistance pot. I need the value of R-31. Curiously mine came from MFJ ~without~ that pot installed and it is necessary to calibrate the SWR to 50 ohms.

Thanks, Brian K3VR

NEW PROGRAM AVAILABLE

TWINTRAP.exe 33 kilobytes.

Two identical plastic insulated wires are close-wound alongside each for N turns on a cylindrical former. The two wires are then connected series-aiding.

Distributed capacitance between wires resonates with the trap inductance at the trap frequency.

Advantages - no high voltage, high current capacitor is needed. And trimming wire ends for exact frequency is much easier and neater than with coax traps.

Download TRAPDIP from website below.

Tom Bruhns, K7ITM wrote:
"Actually, the flue pipe is pretty large diameter, and that lowers its resonance considerably."

Yes it would.

My numbers using a flue pipe length was a speculation because I really didn`t know what the length of the grounded pipe is , much less its diameter, or the effective diameter of a bundle of pipes. It really doesn`t matter much if the pipe(s) are resonating, I described a method of detuning the resonance.

The method of hanging a wire or wires from the upper levels of grounded structures to detune them is well known and used by broadfcast stations finding things like water towers distorting their radiation patterns. They hang a wire or wires from them as I described and the problem is usually fixed. It`s gone. The pattern is as designed or can be if the antenna array is adjusted as designed.

Best regards, Richard Harrison, KB5WZI

Danny,

Thanks - that's exactly what I had in mind, a mixture. But in my case the coax run would be long enough to get away from the house and over to the trees where the antenna is - about 100 feet.

But my reason for going to a balanced feedline in the first place was to avoid high losses in coax under high SWR conditions when operating on bands other than what the antenna is designed for (in this case 80m). If the same loss condition will exist with the double-coax balanced feedline, then that would really nullify my whole reason for doing it. So it sounds like my best bet is to just use open wire (coax just through the wall) and hope my xyl doesn't notice the dangling feedline. ;-)

Danny and the others are right.

Ladder line's low loss under very high SWR conditions (when dry) isn't because it's symmetrical or balanced. The reason for the low loss is that it has high impedance with relatively large conductors -- impedance that's higher than you can get with coax because of the coax's confined fields. Because making a "balanced" (symmetrical) line from coax doesn't give you the high impedance of ladder line, you also won't get its low loss.

I have a 80 and 40 dipole.

No tuner.

If I use CW and SSB equally would it be better to cut if favoring the CW portion because of the higher duty cycle and higher average power of CW?

Currently it is almost 3:1 at 7 MHz and 2:1 at 7.3 MHz.
Talking seems to take much less power.

I have a similiar situation, but more pronounced, with my 80 m dipole.

How come I have a deeper null with my 80 m dipole than with the 40 m dipole. The 80 m dipole nulls to almost 1:1 and the 40 m one only nulls to about 1.4:1?

Got it - thanks Roy. I should have realized all this before I started entertaining the idea. Even using parallel 75 ohm lines only results in a 150 ohm feedline - higher than a single coax run but certainly lower than open wire. Plus there's the extra dielectric between center and braid. All in all, not much better than a coax run.

Any time you go to a small antenna wave lenght wise you do become less efficient. However I have good success with an Inverted-L only 33ft by 33ft and 12 ---16 ft radials. I have 28 states, half ofwhich are east of the Mississippi (I live near Seattle) and 2 Japan contacts and run less than 50 watts. Efficiency wise it probably runs less than 15 percent but it does get me on the 160m band. Oh yes I feed it with 300 ohm line and use a Ten Tec 229 tuner.

One fact I found at this QTH and on the trails is for some reason the Inverted-L likes equal legs tuner wise.

The two legs give you some high angle (for local contacts) and some lower angle for a little DX.

Get a tuner if you want to operate over the whole band.

A dipole in free space is arouund 70 ohms. As you get close to the earth (electrically) the impedance will go up and down. At certain heights the 80 meter dipole will approach 50 ohms. It may be that your antenna is at that critical height. Mine is only about 20 feet up and that is one of the places it is close to 50 ohms at resonance. It sends most of the signal up which is fine with me as I use it mostly to talk to a friend about 200 miles away. Your 40 meter antenna is aparently up high enough where it is around 70 ohms which would be normal and would give you about a 1.4 swr.

I hope I'm asking this question correctly...
What if you had a situation to where you just had to tack up the
feedline say, on the side of a house?. Lets use brick as an example.
And used parallel, properly spaced conductors of RG8X with the shield
floating. The centre conductor size on the 8x is respectable.
Would the outer shield provide any 'isolation' (in respect to
unbalancing the feeder) from the wall, metal window frames, etc?

Art H. Unwin, of Bloomington, IL, has two US patents in the PTO's data base.

5,625,367 Variable capacitance antenna for multiband reception and transmission was issued April 29, 1997 on an application filed on March 20, 1995.

5,790,081 Constant impedance matching system was issued on August 4, 1998 based on an application filed on January 30, 1996.

The PTO's data base only provides the means to search for specific inventors within patents issued since about 1976.

You can get several more db gain by decreasing the spacing
to about 3/16 wl. At least if you can keep losses low enough.

> -Bill WX4A

If, and only if, the currents on the two coax center conductors are equal and opposite (as they would be if you had a truly balanced tuner on one end, a symmetrical antenna on the other, and the feedline was positioned symmetrically relative to the antenna), then there would be no current on the outside of the shield, and you could place the twin-coax feedline against any object without interaction.

Dacron Polyester?

My, the things they sell nowadays.
Used to sell a fiberglass, covered, guy wire/rope back in the 70's.
And for some purposes, I'd hesitate to uses even that.
Rope may be okay for temporary.
Heck, I'm using some old black cloth type fishing line for two legs of my
dual dipole.
But that I consider to be temporary around here.
And no squirrels (unless you consider Gophers to be in that class, and they
don't climb to rooftops).
For a more permanent, I'd tend to say use something like aircraft cable,
done properly with good clamps and maybe thimbles.
I'd not suggest the rope for use in desert type heat like we get here in
the San Joaquin Valley, or hotter places.

I'm using a Rat Shack 2 meter magnet mount.
5/8 wave, and it went through a desert sandstorm East of Barstow CA this year with no problems.
Does quite well.
Can't say about 440, as I have not tried it that way yet, though I could test it with my HT.
Price not bad, and easy to find at most rat shacks.

When you have converted to two parallel lengths of coax for a few inches why bother drilling two holes when one relatively small hole will convey both coax lines.

It matters not a jot how far apart the coax lines are.

So we are now back to square one. Just bring the two feedline wires close together and bring them indoors through one modest hole.

Inasmuch as I do not grock why this works I need to ask a question.
Does the added wire have hang vertically near the grounded structure?
Or can it be connected to it at the top and run perpendicularly?

Ken, KC2JDY wrote:
"Does the wire hang vertically near the grounded structure?"

Yes.

The grounded structure`s resonance comes from balanced capacitive and inductive reactances at the operating frequency. Having no net reactance to oppose current, a conducting structure may have a large induced current in the field of a transmitter. More so when the polarizations are aligned, that is to say when the structure is parallel with the transmitting antenna..

Adding a parallel wire or wires connected with the structure at its top produces induced currents in both conductors flowing up or down simultaneously. These currents butt heads as they continue their flow from one conductor to the other. But they can`t make a complete loop. The suspended wire is left insulated from the earth at its bottom.

Currents flowing in opposite directions in the two conducting paths tend to cancel each other`s external fields.

Try it for youself. You might use a 1/4-wave short-circuited stub (300-ohm twinlead?) with only one of its open-end wires grounded. Put it in a parallel sense with an r-f field producing antenna.. Its effect is the same as that of an insulator in the field.

I don`t reject that assertion without trial. But, I wonder why Terman used 1/16 wl more in his example? The smaller the array, the more the directivity?

The same total power is radiated in the usual case. Only the directivity changes with configuration and current distribution. The picker gets to chose the pattern shape if he knows what he is doing.

Bill wrote:
"Let`s use brick as an example. And used parallel, properly spaced conductors of RG8X with the shield floating."

You have a "balanced" transmission line of some impedance depending on the space between the lengths of RG8X and their outside conductor diameter.

"Floating" indicates that onlty he inner coax conductors are used to make transmitter and load connections. Coax capacitance and inductance couples inside surfaces. These are isolated from the outside surface of the coax by skin-effect except at the ends of the floating coax where the current induced on the inside of the shield can make a U-turn to the outside of the shield, and vice versa. This will allow the outside of the shield to act as the transmission line.

There may be instances of short-length coax where the breakdown voltage of the coax is helpful.

Best regards, Richard Harrison, KB5WZI

Hi StarGazer

Check out my Linear Loaded Inverted Vee for 160 on my web page. It works better than anything else I have tried at my location. Other's have used it, some with results equivalent to mine, others with results not very favorable at all. So I guess it's very location dependent, referring to the ground conductivity it's over. My backyard over years of burying radials is now almost solid metal, hi hi.....

http://archimedes.galilei.com/raiar

Look for the Amateur pages and then the antenna. It has dimensions, pictures and a hand drawing.

> If I use CW and SSB equally would it be better to cut if favoring
> the CW portion because of the higher duty cycle and higher average
> power of CW?

Hard to say really. I don't like to run a solid state rig over 2:1
SWR. So I pretty much have to use a tuner if I want the whole band.
"80 or 40". For me, I prefer to tune so the SWR is below 2:1 in the
fone band. Mainly because I have a larger chance of using an amp
there. I prefer not to use a tuner when running high power. I'll stick
the tuner inline on the cw band. I almost never use the amp on cw, so
I don't really mind the tuner. The loss is fairly unnoticable.
If I had no tuner, I would adjust the antenna for the portion of the
band used at the time. IE: cut the dipoles for the fone band, but have
short wires with gator clips to add on the ends when I want to run cw.
The short wires at the end can just hang, or whatever. Not critical.
There is little current at that point. Of course if you do this, you
must have the ends tied off low enough to reach. You might want to
find a tuner somewhere. Even a small L-net tuner would do the job for
100w use. The small mfj random wire tuner will work fine in most
cases. You don't have to use a high $$$ tuner, although the losses
usually are a bit less with the better coils, etc. As far as a tube
rig, if it will load within the normal loading range, I consider it
good enough. No extra tuner needed. That can extend to 3:1 limits or
better in many cases. If the loading is outside the range, you need a
tuner. MK

I've run twin lead pinched between a nearly closed all metal window
sill and had no problems.
I agree, it's really not that critical usually. Or didn't seem to be
to me. I think the main thing is to be at right angles so the amount
of metal next to each conductor is equal and perpendicular. That helps
keep the balance. MK

What happens to all that "choked" RF?

One time I slid some beads over the wires of a dipole while experimenting with an idea, an adjustable multiband dipole. I applied 100 watts and the beads go hot enough to melt the insulation of the antenna wire.

Mac, I was unaware your e mails were also being posted here.
The reason I was not forthcomming with patent details e.t.c.
is they are a source of embarasement to me.
What I originally submitted bore little resemblace to what came out
as many on this group can attest to.
Patents of mine prior to these have no relevance to the subject at hand.

Mark,
The antenna described was talked about to emphasize what the title
stated.
Instead of auguing the point on this antenna which is presenting a
problem to many. since you say you have made many anttenas have you
ever thought about two reflectors? If you go by what is said in
theArrl books it would say that this would lower the impedance which
gives cause who go solely by the book not to attempt it.were as the
reverse istrue and by now we should have many commercial antennas with
two reflectors. No problem withe good job that the book does
but it is still written that way because of what Reg would call
regurgitation.
If it is written every place it then becomes iron clad fact.
Please dont feel that you have to defend yourself this is not
personal.
Take comfort in one post where it was stated that we reject innovation
that does not come up to the mark, you are in good company.
No offense intended
Regards
Art kB9MZ

The cross-needle watt meter in my MFJ antenna tuner has virtually the same
accuracy as a Bird 43 meter that is in-line at the same time. The MFJ meter also
"reads" faster and quicker than the Bird -- I don't have to pull out my paper
Bird chart and line up the forward & reverse to get the damned SWR. The MFJ
shows it at a glance. I'd recommend the stand-alone MFJ meters to anybody.

Don't believe everything you hear :-)

Dear Art and Group:
I was only trying to provide more detail about the type of antenna
being discussed. Patents tend to be more lucid than what is convenient
to describe here. Patents also usually have drawings that help
communicate.
It is a remarkable achievement that you were able to prosecute the
two patents by yourself. I can not understand, but then there is no
need for me to understand, your expressed feelings about the patents.
Very few patents issue containing just what was in the initial
application.
Perhaps now that the patents have been identified, some investor
will arrive to help move forward the inventions.
Warm regards and keep inventing,
Mac N8TT

Hi Mark, the amount of unbalance introduced by bringing open-wire indoors through a metal window frame at an angle would be negligible in comparison with what occurs due to natural causes in an ordinary well-constructed antenna system.

But it might make a good subject for a 2-page magazine article by PhD. ;o)

Art Unwin, KB9MZ wrote:
"---by now we should have many commercial antennas with two reflectors."

Is that the best use we can make of materials?

Consider the yagi. With only one reflector we can get a good front-to-back ratio. Another reflector in the plane of the radiator and of the first reflector, but to its rear, doesn`t have much energy to work with. The energy is already turned around by the first reflector. A director using about the same material as an additional reflector has a lot more energy to act upon. The logic of a single reflector and multiple directors seems obvious and sound to me.

I have no interest in the status quo.

Theoretically?
Practically, I have also found second reflector to be beneficial (back in late 70ies). At the shorter spacing it gave me better F/B and more gain than I could have achieved with additional director needing spacing about 3 times wider. (Saved boom aluminum.) This was "discovered" by experimentation with real hardware models on 2m antenna test range and with Quad-Yagi combination of elements in my Razors. (Not patented, not commercially manufactured, few built and creamed contest records.)
Pictures can be seen at
http://members.aol.com/ve3bmv/Razors.htm
New software modeling could prove me "wrong" but I can take it :-)

Source record: 137770

I suggested a director might be a better use for more material than using it for a second reflector.

That was based on upping the gain. The dipole with a reflector might give 5 dbd gain. Adding a director might give you 2 db more gain (no guarantees). An additional reflector is likely to give less gain improvement to a dipole with a reflector, as it has little energy to work with.

There are other factors. Front-to-back ratio might be improved using two reflectors, and bandwidth might be better. The dipole with one parasitic reflector has a bandwidth of about 30%. A 3-element yagi (reflector, radiator, director) typically has a bandwidth of only about 6%. Additionl reflectors are unlikely to do much and that includes narrowing the bandwidth.

Evidence of the bandwidth-friendly status of multiple reflectors is probably seen in the TV antennas on British roofs. Many of these seem to have 3 horizontal reflecting rods in a vertical plane if my memory is correct.

A lot has to do with the use that is to be made of the antenna.

Best regards, Richard Harrison, KB5WZI

O. K. Richard it is time for me to eat crow.
! I apologise to all that I have not respoded to, I have only just
realised
that responses are not listed at the end but instead are broken up
into more thread so I apologise to those I may have offended.
2 My focus was on the continuing reprinting of the older wire antennas
for cheapness and then allowing my antenna to dominate the thread
rather than discussion of the title.
3 I accept the admonitions of Roy W7EL as the normal correct ways of
doing things,and I continue to respect his wisdom
4 Believe it or not I have difficulty in accepting why this group has
a problem with my posts. If I knew how to correct it I would but for
some reason I have lost any good communications skills that I may have

had. I certainly recognise that I am not able to follow form and write a paper,posters have certainly made that clear to me but I am unable to correct the problem at the moment.
5 Yes I did speak of this antenna years ago on this thread and I not surprisingly feel it has merit. I also am stubborn continually place myself in a position of scorn. Maybe after today I can reconcile myself that I did the best I could with a product that failed to meet standards.
I apologise for any inconvenience or emotionalism that I have inposed on the readers and will try harder if and when I enter later threads.
With apologise to all
Art Unwin KB9MZ.
I will now read other comments that I may not have read.

Shielded cords may not be worth the trouble and expense. If the wiring of your house is typical it's "non-metallic sheathed cable", commonly known by the Romex brand name. This means the shielding ends where the plug meets the wall outlet, in close proximity to your receiver and all its wiring.

OTOH, if your wiring is in metallic conduit then the shielding extends back to the circuit breaker panel and will provide better isolation. But conduit is more expensive, so it usually isn't used unless required by code (for residences more than three stories high, in most jurisdictions).

I sure like my SteppIR. I have the 3 element with the 6 meter bit. It's
still on a short pole as the tower isn't up yet.
As for the price, I think it's comparable to log periodic dipole arrays and
anything else that can approach the performance.
It's a simpler (at most 4 elements on 6 meters), lighter (lower tower, rotor
costs), stronger (100 MPH),
antenna than anything comparably priced that comes close in performance. The
VSWR is always 1:1.
I think it's correctly engineered and well executed. It does tricks nothing
else can.
I sure hope lightning doesn't find it attractive.

The only disadvantages I can think of are these.

A: a bit on the heavy side.
B: will discolor eventually to most likely green over dark brown.
C: requires good soldering skill, and must be made to exact specifications.

Advantages.

A: has good gain and is fairly easy to construct.
B: can use salvaged copper.
C: parts readily available, most areas.
D: lower cost than aluminum, unless you can salvage the materials from
something else.

Aluminum.
Lighter weight
also easy to construct, but difficult to solder

Either should last long and work well.

Can be built in dual or tri band types as well.
I have seen many web sites with designs for this one.
Seems to be some variance in feed method from one site to another, though
the majority feed center conductor of coax cable to taller element.
This one may be worth a couple of tests to see what if any difference will
come up.
Needs SWR meter or antenna analyzer, and a field strength meter.
to be properly valid, all tests must be in the same locations with the same
power used.

Nobody seems to come up with true gain factor for this type.
Is it that nobody actually knows?

A J-pole has just about exactly the same gain and pattern as a ground plane or a vertical dipole. In absolute terms for an antenna in free space, this is about 2.15 dBi.

For any of these antenna types, current can be induced on the feedline by coupling to the antenna, which can skew the pattern somewhat. The amount of induced current depends on feedline length and placement, but it can be minimized if necessary with a couple of current baluns, one at the feedpoint and one about a quarter wavelength below.

Now you can count yourself among the many people who know. Tell your friends.

Possible idea for an 80-10 mtr vertical/horizontal ant. One 75 mtr hamstick
(7' or longer).
One lead of ladderline connected to the vertical hamstick. The other lead of
the
ladderline connected to 65' of horizontal wire. The other two leads of the
ladderline
line would go to a balun and/or tuner. Does this idea have any merit?

> 2. http://www.ab7sl.com/index.html?row1col2=w9inn.html

Charles,

The structure of the "resonactors" is not clear from the above URLs. However, the W9INN antenna is simply one realization of a trap dipole.

Trap dipoles are no more "high performance" than plain dipoles of the same size. The only reasons to use trap dipoles are the size reduction brought about by the traps and the ease of matching to direct coax feed on several bands.

Reg's software includes concise explanations of the trap constructions. The twin-wire bifilar trap design described appears to result in traps with slightly higher L/lower C/higher Q than their coax equivalents. Much easier to adjust, though.

The twin-wire bifilar trap idea is so obvious - once you understand it - that I'm still kicking myself for not thinking of it! Been using coax traps for 17 years now. (See QST, December 1984, article by N4UU). W8NX did a bunch of coax-trap stuff, including a multilayer thing, but I believe the twin-wire idea is new. Never seen it before, anyway.

Next time the antenna needs work, I'm going to try some twin-wire traps. PVC pipe and the center conductor from RG-58 scraps...gotta luv it.

Reg, you should write the thing up for the ham mags.

Hello,
The apartment I live in does not allow antennas to be put up unless the are hidden. I would like to know if anyone could tell me if there is a website or book I could get that discribes how to make one. What I was thinking was, if possible, making a coax lead that would go to basically just a copper(or some kind) of wire that I could streatch to look like a wash line in the back yard. Can anyon e give me help on this.

Thanks,
Mike Waters

33' ALUMINUM TOWER FOR SALE - This is a old heavy duty aluminum Navy "Loran Transmitter" type. The tower is assembled with total length of 33 ft., with hinged base ready to mount on concrete base. Tower is 12" on each side, ladder steps on one side. Approximately 55 lb.'s weight. This is not a self-supporting tower, guying or dwelling bracketed recommended. Has flat plate on the top, ready to cut for the thrust bearing (pilot hole centered). Has rotator support plate mounted 5 ft. below the top, will need mounting holes drilled so match rotor base. Pickup in Chesapeake, Va. 23323, or deliver Tidewater area within 35 mile radius.

I am looking for info on what everyone's past experiences are w/ types of
coax, and recommendations for the following antenna types.
I am installing a 100 ft tower, w/ 6 antennas.
The antennas are:
VHF base station 6db gain (commercial use, for a repeater)
UHF base station 9db gain (commercial use, for a repeater)
Dual Band base station ham antenna (possible repeater at some point)
VHF Yagi on rotor
UHF Yagi also on the rotor
Low band base station antenna

Discone scanner antenna on the roof peak.

I'm not looking for extreme quality here, but of course as the saying goes,
you get what you pay for..
Cables will be buried in PVC pipe.

Thanks

Jeremy

If all other characteristics are the same, is there a difference between a split (snap-on) ferrite core and a solid ferrite core? In other words, does the fact that there is an electrical open between the two halves on a split ferrite affect any electrical characteristics?

On the same line of thought, if I glue together two, three-inch ferrite bars end to end, would this be electrically the same as having one six-inch bar?

Thank you.

The Group
Before we get too deep with this offshoot regarding two reflectors, where I have probably overeached to support my other statements, consider the following.
There is no doubt in my mind that for present HF antennas and the like, two reflectors has yet to be proved beneficial. For moon bounce and the like of which I have no experience modification of radiation pattern and impedance are paramount. In an experiment which I performed and on which Roy W7EL graciously placed on his page a simulating program of the antenna which consisted of 13 elements including reflectors, where it was shown densely populated element antennas provided no extra gain over those presently in use (tho in my mind they had no less gain)and the only thing for that particular HF antenna, was that the second reflector element produced a HIGHER impedance!
Since antenna manufactures make great note of improving for gain on the status quo creats unuseable LOW impedances at least for HF antennas. I extrapolated perhaps incorrectly,that the two reflectors may well have value where gain is everything as well as the radiation pattern, ala moon bounce antennas.
But if a statement is made where the use of a second reflector IMPROVES the pattern then the question of adding to the statement LOW impedance is up for question.
As I stated earlier, I may be over reaching in using this as an example and I also do not have experience in areas above HF .

On another side note with respect to aluminum clad fishing poles, there is in present day use pre adhesive coated aluminum which is used in the building arena for long term use which allows for elements with zero number of joints for those cases where the joint resistances is bothersome. In addition for those who have to have a joint, most hams have seen at hamfests demonstrations of the use of a blow torch and a suitable 'stick' for want of a definable word connect aluminum rods to .002" thick alumanum wrap with little difficulty, but to each his own. It is undeniable that for those with little cash on hand that telescopic aluminum for ham use is extremely expensive and where a search for more reasonable methods and costs are in order.
I have taken extra care with this post but it probably wiil still confuse most readers if past experiences are taken into account.
If it does, please let that part of the subject to drop and allow the use of two reflectors to pass away from this thread.
Thank you for your indulgence.
Art Unwin KB9MZ

One note of caution, the above might valid in simple, few element antennas. Antennas with more than 5-6 elements start losing F/B and this is when second reflector comes to the rescue and offers some benefits. The 15m Razors shown at

http://members.aol.com/ve3bmv/Razors.htm
have configuration: Yagi reflector, Quad reflector, dual Quad driven log cell, Quad director and 2 Yagi directors on a 62 ft boom.
I played with that stuff on the 2m antenna test range for three months during long Canadian winter nights and that was the best I could come up with. More emphasis was on the clean pattern (best F/B and F/S) rather than max gain. They are practically flat 1.1:1 across the band.
I am trying to find some free time to plug the Razors into the EZNEC, but QRL with resort is in the way. So far I tried to compare my 3 el. Quad design and simulate it in the software and there was some discrepancy. I ran it also through AO. I need to do some correlating with 2m models (much easier than with real HF antennas) and see what I get.
So far when some friends tried to do multielement Razors in software, they tell me that they have no gain and lousy F/B and pattern with high angle back lobes. Well, I have seen real antennas performing on 2m (compared to KLM "standards") and then scaled to HF and I know how they work. I am looking forward to explore this, just need to shake off the QRL.

1959. G5RV, coax/ladderline and remote tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-30 17:37:04 UTC
From: a_g_lyph@hotmail.com
Message-ID: <f8479612.0207300937.7321c204@posting.google.com>
Source record: 137800

Hello-

I managed to get a G5RV about 22-24' up in the air a month or so ago and it has been working wonderfully. It is currently (no pun intended) fed by approximately 80' of Belden 213-type coax, which is connected to an Emtech ZM-2 tuner which is connect to the rig by a short jumper. So far, so good. Even had some success at QRP during the WTRC weekend, using my FT-817.

In planning for the coming cold weather, however, I would like to extend the feed into the house. I'm not terribly excited about having the tuner at the rig, as I'm concerned about RF on the coax feeder running out to the antenna. What I'm considering, and what I would like comments on, is the possibility of using a remote antenna tuner, say an SGC-239 or LDG RT-11, mounted to the side of the (wooden) shed which the ladderline from the G5RV hangs next to. From looking at the SGC literature, I can use an 4:1 balun to go between the tuner output and the ladder line. So, I would have:

rig -> ~80' RG-213 -> [SGC-239 | RT-11] -> 4:1 balun -> ladderline/G5RV

Is this a logical approach or is the remote tuner directly to ladderline not advisable? Is the balun necessary? Am I missing anything important here?[1]

Assuming this is a logical solution[2], any comments on the SGC vs. the RT-11?

Many thanks in advance,

AG

[1] I'm sure I have, be gentle... :)
[2] Well, even if it's not, I'd still like to hear input on the two ATUs

Gordon, two questions:

1. How do you connect the coax and the open line feeder - balan or no balun?
2. What is the VSWR on the coax on the various bands? Where did you measure it?

Malcolm

AG,
Forget the 80 feet of coax. Mount the tuner
to the outer wall of your operating position.
Run ladder line from tuner to the antenna. Run
coax from the tuner to the radio. If the ZM-2
will handle ladder line with/without a balun,
forget the SGC.

>How many Hops on 40 m from coast to coast??

I theorize that the answer might depend on the height of the ionosphere.
Perhaps the higher the altitude of the ionsphere, the lesser the amount of
skips you need for a coast to coast qso on 40m.

I figure you'll get a lot of responses.

Brian,

I have the 249B, and I'm not sure if they made some circuits changes but it looks like nothing short of dissambling the entire unit to see the component values. I wish I could help but mine is less than 2 weeks old, and I would hate to do irreversible damage. Might be better to call MFJ.

Good luck,

Max

Using the computation from an old NBS Time and Frequency Users'
Manual, the minimum distance path from San Diego, CA to Augusta, ME
is 2 hops. You can get from San Diego to Detroit in 1 hop in the
winter, and perhaps as far as Connecticut in the summer.

This is based on the assumption that the average F2 layer (virtual)
height varies from about 250 km in the winter to 350 km in the summer.
There are day-to-night variations as well which aren't mentioned in my
reference. The higher the F2 layer is, the further you can get in
a single hop.

It depends on the effective height of the ionosphere, which varies with frequency, solar flux, and time of day.

The easiest way to determine the number of hops for a given time and frequency is to download the excellent, and free, propagation program W6ELProp by Shel Shallon, W6EL. You can get it at http://www.qsl.net/w6elprop/. It's easy to use, and will give you the information you're after.

>What is the best all-round antenna for HF work, 80 to 10 meters?

Well Dave, In my opinion, a 125' dipole fed with open wire or ladder line as high as you can get it. An antenna tuner or transmatch to match the line to the rig. 80-10, good efficiency. The pattern of this antenna gets strange above 15m, but as with all antennas, can't have everything.

My vote is for two. A dipole fed with ladder line and an inexpensive
vertical tuned with a base loaded coil. There am times when it is sure nice
to switch!

Go to google.com and do a search for the J-pole antenna. If you look around, you should be able to find one you can make from inexpensive TV twin-lead. Hang it in your window, and it should hit most, if not all, of your local repeaters. You could also get a copy of the ARRL Antenna Book, available at http://www.arrl.com This book has all kinds of vhf antennas, and will teach you the principles of antenna-building.

Build a J-Pole, I used 450 ohm ladder line, but you can use 300 ohm twin lead. I enclosed the antenna in 1 1/4 inch PVC. My walking stick antenna was the hit of the K2BSA staff at th 1993 National Jamboree. A VK worked a ZL with it.

> 1. How do you connect the coax and the open line feeder - balan or no
> balun?

Presently, the setup is as follows:

rig -> short coax jumper -> ZM-2 tuner -> ~80' coax -> ladderline

The G5RV ladderline piece is connected via a PL-239 (or is it SO-239,
I always get the two backwards) connector mounted on an insulating
board (phenolic) which has the ladderline connected to it.

> 2. What is the VSWR on the coax on the various bands? Where did you
> measure it?

Hard to tell as I don't currently posses an VSWR meter. The LED on
the ZM-2 and the built in SWR meter on the FT-817 are the sole means
of monitoring such. As the rig is connected to the ZM-2 tuner, the
built-in meter is measuring the VSWR between the rig and the tuner on
the short jumper of coax.[1] The LED on the tuner is measuring the
VSWR on the coax/ladderline section[2] and on 10m, 20m and 40m I can
get the LED to black by adjusting the varicaps (sometimes kicking in
the 250/500pF adjustment, sometimes not). I haven't really tried it
down on 80m and I don't believe the G5RV will handle 160m without
being fed differently.[3]

Hope that helps, but I suspect it doesn't.

AG

[1] Or so I believe
[2] Or so I believe[4]
[3] There are instructions on the Internet for making this happen;
I hope to have replaced the G5RV with something else for the
lower band by the time I want to play down there
[4] I am well aware that I could remain silent and (only) be thought
a fool. However, I am hopeful that by expressing my beliefs
regarding what is happening, the resident gurus might share a
little light with me...always searching for more light.

'Doc-

Thank you for replying. I understand your suggestion, and the ZM-2 will handle balanced feeder by using the binding posts and switching the unit from 'ground' to 'link.' So, mechanically, that would be attractive. Unfortunately, due to the placement of my 'shack' inside the house, and the necessity of mounting the antenna on the far side of the rear yard I don't think it will be logistically possible. My XYL would frown heavily on my bisecting the yard with ladderline. =(

I was originally thinking of sinking PVC pipe into the ground between the exit point of the 'shack' and the feed point of the antenna. Now, I'm wondering, though, if I couldn't just run the ladderline through the PVC? I know that the ladderline portion of the G5RV is a part of the antenna system and I believe that it resonates (at least on 20m). Would using a long run of ladderline, underground, encased in a suitable diameter PVC pipe present any problems?

Now that I'm thinking aobut it, though, I would wind up with a balanced fed, 102' dipole at 22-24' in the air. I could actually lengthen that to around 125' if that would make a difference. I wonder how that would work. This hobby sure is a hoot!

Thank you again for taking the time to reply.
Regards,

AG

AG,
Off hand, I'd guess that running ladder line through
a buried PVC pipe wouldn't work. But I'm certainly not
sure about that! That would be interesting to try. If
you could keep the ladder line 'centered' in something
like a 4" pipe, I wonder if it really wouldn't work?
Hey, try that and let us know! (waiting with baited(?)
breath)

> Brian,
If it is used for calibrating the meter i.e. it is before the meter
and in series with the output of the meter going to ground my guess
that 100k
would be satisfactory.Frankly I have a problem with the idea that the
pot is missing as the meter would be useless as in such a case the
meter would be out of the circuit. Why not trace the circuit around
the calibration meter,it may well be that there is another circuit
between the meter amplifier and the meter which would suggest that the
particular circuit board has multiple device useage
which in your case is not a feature that your device is produced for.
Sorry I cannot be of further use.

Unless you're dealing with a really high permeability ferrite the
small gap where the cores meet isn't a big concern. It's a concern
with high permeability Manganese-Zinc ferrites (mu of 5000 and up),
but not the lower mu RF materials.

Some very high mu split E cores have finely polished mating ends, to
cut the air gaps down to the bare minimum possible. To obtain their
high AL values these cores need to be clamped together, not glued.

But if you're using the typical type 43 Nickel-Zinc ferrite for RFI
suppression, the gap doesn't upset the permability very much (probably
less than the tolerance of AL). You won't notice it.

Any rod configuration has mu determined mainly by the rod geometry.
The disturbancve of the magnetic path caused by gluing the rods
together is nothing compared to the air path between the ends of the
rod. This is why the rod's AL so stable, much better than the
tolerance and temperature coefficient of the ferrite itself.

It also depends on the radiation angles of the antennas at both ends.
You may not be using the minimum possible number of hops if your
antenna works poorly at the angle you need for those hops. The signal
may be stronger with more hops, arriving at an angle better suited for
your antenna system.

Likewise, there is a maximum number of hops. This can be limited
either by the MUF for the path to the closer ground reflection or by
the cumulative losses of all the hops.

Gordon, it appears to me that moving the tuner to where the insulating board
is will certainly not make anything worse. However, the tuner, even though
it would be floating is still 'one-sided'. So, I would either use a balun
or build/buy a tuner with a truly balanced output. If it were my
installation, I would check the VSWR at the coax/line junction. If it is
not too (?) high, I would install a balun, a real one not a choke. If it
is high, then you will have to acquire a tuner with a truly balanced output.

Good luck,

Malcolm

Howdy,

No doubt about it. A half wave doublet 130 feet long fed with low loss balanced transmission line, open wire or transmitting twin lead. You will need a"tuner" with a balanced output.

On 40 it will be a full wave and have gain.

On higher bands it will have lots of lobes. Make sure it is at least 40 or more feet off the ground.

I have lots of antennas for HF and this one is excellent.

A half wave dipole for 80M centre fed with 600 Ohm
balanced line. If you have a good ground, you can
tune one side against ground and use it as an
inverted-L on 160M.

Hi all:

Everyone recommends a vertical for limited space, but a vertical is NOT an limited space antenna especially if used on 40M and longer. Those radials take up a lot of room. I've been reading ON4UN's book on low band DXing and its clear that a vertical takes up more room than any dipole, if you want it to work well, or at all. While the visible part of a vertical is small the area that it takes up is not.

Dave wrote:
"What is the best all-around antenna for HF work 80 to 10 meters?"

Commercial and military radio suppliers usually come up with the base-loaded vertical whip as their answer.

It fits a small space.

It is nearly omnidirectional.

It works over the wide range.

The loading coil can be made mechanically secure. It can tune out the reactance of the antenna to maximize antenna current.

The vertical antenna broadcasts in all azimuths. If you can`t predict a desired direction, omni capability is best.

See page 7-14 of the 19th edition of the ARRL "Antenna Book" for details, or see page 491 of the 18th edition of W6SAI`s "Radio Handbook".

John Passaneau wrote:
"Everyone recommends a vertical for limited space, but a vertical is not a limited space antenna---."

Limited space limits performance.

The vertical can make good use of a 1/2-wave diameter circle containing many radials but this is most often compromised and the antenna still works.

Just look at whips mounted on vehicles. These often have small footprints.

Oh not arguing the price, its a neat beam and with the technology, most
likely well worth it, and if it becomes popular then the price may come
down. Just outta my reach right now HI.

> It's a simpler (at most 4 elements on 6 meters), lighter (lower tower, rotor

Thats what I like about it. Especially the 6 mtr part. Im limited in
cable runs right now and the 3 I have are the A3 the 80mtr and the
2/440. And the fact that it does 17 and 12 meters as a beam is a plus.

But how are you going to turn it when the other person is in one of
the many nulls of the radiation pattern ?.If you solve that and could
turn the antenna to remove the person from the null then you have a
BEST antenna! Does the horizontal polarisation of the antenna provide
better coverage overall than when
it is used as a system? I.E. use of the feeder to generate vertical
polarization. In other words what are the all the advantages and
disadvantages
that make this the BEST antenna.

very good job with your page. I envy your ability to do such fine work
I could not read some of the pages because of the small script but as
you said ...work in progress.I found the idea of a pole that elevates
with the use of the bicycle interesting and also envy you for being
able to spend time in that wonderful county of Suffolk. I spent some
wonderfull times there in my childhood where the jerries destroyed our
home in East London and we had to wait for one in better state of
repair.i.e. huge timbers to stop the side of the house falling was the
best we could get. But Suffolk was so quiet and beutiful.
To this day I dream of the old church yards, the sugar beet fields and
gleaning
in the wheat fields. As I said,great job.

Long responses to questions here may not be well received even if well considered and the responder has the time and energy to devote to the response.

Information in the Antenna Book has been checked, rechecked, then checked again, as they say of the tabloids here. My opinion may be suspect for a variety of reasons. The Antenna Book, on the other hand as Art Unwin noted, reprints much of the same information in edition after edition. Any significant mistake has probably been edited out, according to our understanding of the principles now.

I believe many readers can avail themselves of the Antenna Book or an equivalent. I gave a page number for reader convenience, but the same information can be found elsewhere. That`s up to the reader.

I Would not throw out the PVC pipe idea. I have never regreted the 6
inch dia PVC pipe that I put under ground as it gets all the wires out
of the way.
I would suggest that you also place a steel wire (1/4 dia) for the
length of the pipe portion to allow you to add replacement control
wires for the rotor and for any other control wires you may need in
the future for further experimentation (ie a means for pulling thru
new wires).
You have a lot of antennas on that tower and if you do not use a pvc
pipe for the underground stuff then look at Murphy siiting on the
fence with that grin of anticipation.I also use 7'8 dia Andrews coax
all the way to the tower top.

2013. Re: Best Allround Antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-07-31 17:41:49 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ai97gs$r0a$1@paris.btinternet.com>
Source record: 137701

If you think the nulls in the radiation pattern of a dipole in the
horizontal plane are much like the theoretical, pretty patterns generated
produced by Eznec then have another think, Nothing is perfect. Radiation
from the feedline, reflections from the ground and the oceans, and other
propagation and ionospheric effects fill in the nulls. For practical
purposes a high dipole is omni-directional.

Art, if you can't propose a better antenna other than trailing a wire from a
spool behind a jumbo-jet, it must be assumed that what has been proposed and
used by 100's of thousands of others world-wide is indeed the best.

I havn't seen any noisy protests from G5RV supporters.

==========
Richard, I quite agree. It is completely ineffective for whatever the intended purpose might be. Of course, the polyethylene would provide the essential high-voltage insulation.

Well I am glad you like it. It sure costs a lot of money, $1000 was it?.

For my money I would want a bit more gain on all frequencies and less complexity
in the moving parts area.I think I would rather make my own antenna to over come those problems. For those who cannot afford it using the old (20 years plus)
automatic antennas used on euro cars such as the mercedes 300 will do the same job at a much less cost. Only the rich could afford those car antennas in the old days but now the scrap yard sells them for around $20. Of course you can make your own antennas instead of buying and following their style of design you can produce a much better technical spec'd antenna for much less money.
If I was the IR componey I would work quickly to get rid of the step motor drive and its complexity before sales drop off completely but I am sure they are doing just that ?????

>does
>the coil need to be switched out?

Hi Alan, The shorty fourty once tuned for 40m probably won't work on other bands. If you made the dipole elements about 22' instead of 18' and fed it with 450 ohm ladder line, with a suitable tuner, it would work well on 40m-10m.

I have a Sony SC1 scanner which as you know can be switched to different modes (NFM, WFM, AM) in any band. Since it covers the 225 - 400 MHz band and can be switched to NFM mode, I would like to try and listen to FLTSATCOM satellites.

a) My first question is what would you recommend as an antenna and a preamp (I've heard that you need a preamp to listen to some of these sats)? Price is always a consideration but if you can give me options that work I'm sure I can find the prices for new/used antennas or preamps.

b) My second question is whether there are any other sats that I can listen to. I'm not interested in the WX sats, so anything other than that and using a freq below 1300 MHz.

AG wrote:
"I`m wondering if I couldn`t just run the ladderline through the PVC?"

Buried plastic pipe would sap significant energy from ladderline unless the ladderline could be contained far away from the pipe. The distance needs to be many times the line spacing because the earth, unlike shielding on shielded-pair r-f cables, is usually very lossy.

The 19th edition of the ARRL Antenna Book suggests paralleled lengths of RG-63 (125 ohms) for a balanced line of 250 ohms that can be routed with little regard for the surroundings. (See page 24-20)

Best regards, Richard Harrison, KB5WZI

Hello All,

Just moved to a new place in the mountains. Set the discone on a 20' post and received Los Angeles, 125+ miles away.

The only place for a permanent mount is on the back porch...right where a tree is growing! I've got the pole mounted in between two large branches that are growing out from the tree and away from the antenna. All the limbs surrounding the antenna are about 6' from the pole and the radials.

My question is: monitoring C.D.F. on 151 MHz and perhaps 800 MHz later on, is there a potential for signal strength loss by not pruning the limbs back? Will the limbs cause major reception/interference later on?

It's really a beautiful tree and I'd hate to prune it way back if it's not necessary.

Many thanks for taking the time to respond!

Alain...somewhere on Palomar Mtn. (where the 200" telescope is)

When making a J-pole antenna, does the shield go to the stub or the long length? I've seen it both ways. It seems to me that since your feeding the stub the shield should go to the long length and the center conductor go to the stub.

Various searches and various magazine articles show it both ways.

Thanks and 73

That would be extremely dificult to do.
I was thinking that he would use a switch box at the tower top.
My PVC pipe has three coaxes running in it plus an untold number of
vaious
control wires which occasionaly get tangled up when I add to them.
> All that I was suggesting was that the Heliax is good for direct
> burial.
I would agree with that, but if he has other wires such as for the
rotor e.t.c
and the tower is a long way from the shack the wife would be very
happy to see those wires hanging in the trees put out of sight
underground. Anyway ythat has been my experiences over the years.

> Yes but what is it that you value about the G5RV ? There are other antennas
that are multiband or for that matter multi frequency. Even a loop
antenna
can be turned to a station that is in the null of the G5RV. Yes, the
interchange will be weak where with the G5RV it would be impossible.
If a dozen or so hams were to list what they would want from a
multiband antenna
my guess that would be an all round radiation pattern which points to
a vertical or, in the case of horizonatal polarisation it must have
the ability to turn
The G5RV has none of these attributes so what has the G5RV have to
warrant your enthusiam over other antennas ?

Well if we keep the boom length to managable 200 feet, and fudged the
lower frequency to 3.5 MHz, we could use 15 elements and get a bit
over 8 dBi throughout the range. That's 3 element Yagi territory.
This isn't great but by going QRO with a Henry 8K, you should do okay.
I think a five-inch gun mount could rotate the whole structure without
trouble.

The tower height is kind of low, but it won't require lights at this
modest height.

Too bad Frank, W6KPC, sold the farm and moved to town; he could have
tried this.

2035. Home Use of J-Pole

Consider two scenarios. A city environment such as NYC and a country environment with large hills, not mountains. If one is looking to improve their FM reception, would a JPole be effective in both cases? Are there better options considering that this would be a DIY project?

Somewhere I have a copy of Isbell's original article on the LPDA filed
away, however W8JK's book "Antennas" has some design information.

Using one of his examples, I ran the numbers and came up with a boom
length of 325 feet and 16 elements with lengths ranging from ~13 feet
to ~190 feet for a gain of 7 dBi.

Anybody want to calculate the wind load?

73,
Bob Nielsen, N7XY

Source record: 137726

Field strength E' at distance D metres from transmitter with Pt watts power output, and antenna gain Gt is -

E' = Sqrt(30 * Gt * Pt) / D volts per metre.

When a field strength meter is used at the other end of the path -

E' = 68.83 * Sqrt(Gr * Pr) / Lambda volts per metre,

where Pr is the matched receiver input power in watts, Gr is the receiving antenna gain and Lambda is the wavelength in metres.

The above pair of equations can be combined to describe the overall Tx to Rx path. Receiver input power for given transmitter output power turns out to be -

Pr = Gt *Gr * Pt * Square(Lambda / 4 / Pi / D) watts,

which, of course, is a reciprocal relationship and is easily converted to S-units. You can't have a linear transmission path which has a different loss in the other direction of transmission. Antenna gains are relative to an isotrope. The gain of an isotrope is 1. D is the straight line path length. Modify path loss accordingly for ground and ionospheric paths.

The foregoing is beautifully simple and is exact, easily understood by anyone who can do arithmetic. Every radio amateur worth his salt should be familiar with these basic concepts. But I've never seen anything of the sort in any so-called educational periodical, annual or compendium. (I havn't bothered to look lately.) Is this because technical editors and authors don't understand it themselves ? Or is it because ancient Elizabethan measurement units mixed with metric units result in frightening expressions?

It has been said elsewhere on this newsgroup it is time handbooks were re-written. Regurgitation of the old stuff by plagiarists, forever continuing popular misconceptions, will condemn the hobby to history, as interesting as the history of radio may be. Publishers have other objectives.

Except by saying we should get into the 21st century I don't know where we should go from here. But there is a serious handicap in whatever direction may be taken. And that is a general worship of the computer program. Any rubbish produced by a computer is willingly accepted as the gospel truth. Having lost or never had the ability to be logical or critical some people will manage to digest anything. Victims of antenna and SWR meter salesmen!

I remain optimistic. What are the Chinese doing? Good night dear friends.
;o)

Yours, Reg, G4FGQ

2039. Re: Dipole question? How much shorter one side than other?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-01 01:29:52 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D488F10.4020100@eznec.com>
Source record: 137727

These things will appreciably affect a dipole's pattern, gain, or efficiency. They will affect the effective length, so if you're intending to make the dipole resonant so you can feed it without a tuner, you might have to adjust the length to compensate.

Source record: 137728

StarGazer asked several questions about antennas being used in the wrong bands.

An 80m band dipole will perform better in the 160m band than does a 40m band dipole because it is less deficient.

If you have a good ground, the dipole and its feedline can almost be operated as a "T"-antenna against that ground connection (short the balanced line). This is a vertical antenna with a capacitive hat. Given the proper feedline length, this "T" antenna can be resonant in the 160m band though the dipole is cut for a higher frequency band.

A 40-meter band dipole will have fewer lobes than an 80-meter band dipole when operated on 10 meters. The better antenna happens to have a lobe in the direction of your target. This disregards the strength of the lobe and the interference to be found in reception from lobes which are not on target.

Best regards, Richard Harrison, KB5WZI

Perry Mason wrote:
"A city environment such as NYC and a country environment with large hills, not mountains."

For FM reception, a J-pole is likely not best for VHF music or amateur service.

In the city, multipath reception is a problem due to ample reflecting surfaces. Highly directive antennas sometimes make reception tolerable where destructive interference poses problems with non-directional antennas.

In rural sites with hills, you may need antenna height for line-of-sight and directivity for signal strength.

Both scenarios often call for directive antennas. The J-pole has no discrimination at any azimuth and has a little less gain than a dipole, ground-plane, or coaxial antenna, typically -2dBd, according to Arnold B. Bailey who holds U.S. Patent 2184729, 1939, on the coaxial antenna.

Best regards, Richard Harrison, KB5WZI

Henry,

I attached the shield to the 19" stub, center conductor to 57" side and I have no higher than 1.2:1 SWR across the entire 2m band according to my 249 analyzer.

Source record: 137738

My experience with copper pipe J antennas is that when directly connecting the coax to the outside of the pipe, rf current on the outside of the feedline is a little lower when the coax is connected with the center conductor connected to the quarter wave stub and the shield connected directly across gap on the long leg. I also found that using a half wave balun did not seem work any better at decoupling the feed line than just directly connecting the coax. The location of the direct coax connection is a little lower on the stub than with the half wave balun but not as much as you might first guess. Not using the balun has the advantage of providing a DC path between center conductor and shield reducing static buildup. To the initiated, it looks like you are trying to feed a dead short.

Also a quick hint. I used liquid flux to solder the coax to a pair of screw type metal hose clamps. Slip the hose clamps over the copper pipe. You can then easily adjust the feed location. Center frequency of the antenna can be adjusted by changing long leg length or slight changes in the spacing of the stub opening.

The fields from a twinlead feedline extend some distance from the wire. It seems to me that if you shield each wire and tie the shields together but otherwise float them, the fields will be confined to the insides of the shields -- *IF* the currents in the two twinlead conductors are equal and opposite. And if they are, placing the outside of the shields against a conductor should have no effect on the twinlead currents. This wouldn't be true of twinlead without the shields. Of course, if the currents are unbalanced, the difference current will flow on the outside of the shield and will couple to other objects.

Or am I missing something?

The specific point I was addressing seems to have been answered...a
floating shield would tend to act in harmony with the actual centre
conductor.
The idea was to ask if the configuration would give leeway to an open
line tacked up against a wall and if the coaxial shield in between would
offer any benefical isolation simply by its prescence.
I'm convinced that it wouldn't.

That logic works both ways, so how about deliberately forcing the
difference current towards zero? That could be done either by winding
the double coax into a bifilar choke, or by threading both lines
together through a string of ferrite beads.

By discouraging outer-surface currents on both shields, it should be
possible to force the currents on the connected twinlead to be more
exactly equal-and-opposite; in other words, to discourage common-mode
currents on the twinlead.

I apologize -- I thought we were talking about a twinlead conductor. For a single conductor, I agree entirely with what Bill and Reg said -- a floating shield wouldn't help. The current on the outside of the shield would simply be the same as the current on the wire, so the coupling to it would be the same.

So I was missing something. Thanks.

I think I get the gist of the question(s). Doc, not everybody has done wire ants before and may not have that 'gut' feel of how many inches can be fudged...although it may be questioned 'why fudge?'
That being said, if you measure per the formulas then it will usually work. An inch or few at 3.7 MHz is pretty irrelevant. Depends more on how picky you are rather than performance.
This bizness about spiral wrapping the ends that don't fit is a tricky subject. Suffice to say it can be made to work but don't bother looking for charts and stuff to tell how to do it. Makes more sense just to let the excess wire hang free.

Yes, that is what I did. Sure there is a discontinuity, but it is physically small compared to a wavelength on HF.
The reflection from the beginning of the discontinuity will be cancelled by the one from the end because they are in opposite phase and the phase difference induced by the length of the discontinuity is negligible.

>
> Don W.

Hi Don,

Thanks for this good idea. Availability of the AD8314 is no problem,
the representative over here is happy to send 2 samples.
The Murata coupler however is another story. Although Murata
have their European warehouse just around the corner, they can
not deliver the coupler in small quantities, neither can their local
representative. Moreover, the coupler you suggested is VERY
small, .08 in x .05 in. And within this footprint 8 terminals to be
soldered. That's way out of my SMD soldering capability.
Do you know of any alternative more readily available and larger?

Thanks again for your follow-up.

Cheers,

Sam

Hi Peter,

You are clearly frustrated, but I don't see how the comments lead to the subject.

You might try Steve Best, VE9SRB, who has helped other folks on this forum in the past on this issue.

I suspect he is on here, or maybe a friendly call to him would do it.

There are some intense rumors floating about regarding an antenna company north of Boston, but I have no factual information. Especially since there are a dozen antenna companies North of Boston...not to mention a few to the West and South!

The Cushcraft R8 has no burried radials, and the counterpoise radials
are much shorter than 1/2 wavelength, I beleive they are about 1 meter long.
The construction is 8,7 meters high and take less space than the 80-meter
dipole. (You need a larger property to span out a 40 meter long wire.)

The R8 is reported to be a better DX-performer than the dipole,
mainly because of its lower radiation angle.

Peter,

I don't know what the problem is but it seems like Cushcraft is joining the ranks of MFJ. Some think their quality and service is great while others think it sucks. Check out eHam.net under product reviews for the MA5B Beam. There is a recent posting of a fellow who had trouble getting his to work and got good results from their service department. They determined there was a defective part and and sent him a new one. Maybe you can contact him and find out the "secret to his success". Myself, I had good relations with their service department regarding a R5 Antenna, but that was 10 years ago. Good luck.

Source record: 137759

BM,
I may have misunderstood about the wrapping of wire
at the ends of a dipole. If it's done to increase the
dipoles length, I'd say it would be a waste of time, cuz
it doesn't. If it's done for convenience, while adjusting
length, then sure, why not. When it's wrapped back on it's
self, it effectively 'disappears' as far as the dipole is
concerned. When you're satisfied with the length adjustment,
and you don't feel like cutting the 'extra' length off, it
won't make any practical difference in performance. And if
you decide to operate at a lower frequency, it's much easier
to 'unwrap' a few inches than solder more wire on. If you
let the 'extra' wire dangle, it does become part of the
antenna's length (to some extent depending on the length of
the extra wire and the 'angle of the dangle').
The 'classic' formulas for dipole length have a little
'fudge factor' built into them (less as the frequency goes
up). The length will almost always be a bit longer than really
needed (easier to cut off than to add on). A very coarse rule
of thumb is that you will have some extra length equal two the
first one or two digits of the band the dipole is cut for, such
as '8' inches for 80 meters '2' inches for 2 meters, or '16'
inches for 160 meters. At least that's about what I've found
from experience with wire antennas. The treatment of the ends
of a wire dipole aren't really ~that~ critical at HF.

I was right first time.

It is obvious receiver input power increases in proportion to both Tx and Rx antenna gains, so -

Pr = Gt *Gr * Pt * Square(Lambda / 4 / Pi / D) watts is correct.

However there's a similar error in the equation for the field strength meter.

When the dust has settled I'll go back to square one and tidy-up all 3 equations.

Proves my point about not believing everything seen on computers.

Roy Lewallen wrote:
"Does Bailey say how this gain is determined?"

Glancing about doesn`t show me a description of how the data were determined.

Bailey provides a catalog of common antenna types. It includes a sketch, polar pattern diagrams in 3 mutually perpendicular planes, directional type, polarization, description, size at 200 MHz, transmission line recommendation, surge impedance (before reflection), resistance at 200 MHz, 200 MHz gain referred to a dipole, bandwidths for 1 db down and for 3 db down.

These are included in a remarkable book "TV and Other Receiving Antennas". Bailey tells how to determine antenna characteristics but I don`t remember a description of how data were obtained for his catalog.

For each antenna, Bailey gives references. For the "J" or "Zepp", Reference:
Zenneck,J., and Selig, A.E., "Wireless Telegraphy," McGraw-Hill Book Co., Inc., New York, N.Y., 1915; p. 163.

From what I`ve seen, Bailey is hardly more error prone than Terman. I would start with the assumption that what he has in his book is correct until proven wrong.

Source record: 137766

Assuming it's 3000 miles from coast to coast, at 7 MHz in daylight along the whole path, propagation will be via the F-layer at a height averaging about 300 miles. At this height the greatest possible one-hop distance is about 2000 miles. So 2 hops would be needed in daylight.

In darkness along the whole path, the F-layer falls to a height of about 200 miles, so 3 or 4 hops would be needed.

As the number of hops increases so does the path loss due to the loss at each reflection from the ground and from the ionosphere.

Whether communication can be established depends on ionospheric conditions. These depend on time of day, sun spots number, season of year and the 11-year solar cycle.

Reg,

Too bad the error was discovered and corrected so quickly.

I thought we were onto a real breakthrough. The incorrect equation would go a long way toward explaining how manufacturers of mediocre or poor antennas could claim high gain figures.

Seriously, however, your equation is not really new or unknown. It appears to be exactly the same as the Friis transmission formula, dating from at least the 1940's. This is covered in professional and academic texts, but perhaps not in amateur publications. (I assume you already know this quite well.)

Why is it seemingly ignored by the amateur? Who really knows, but it might be that the equation is not terribly useful for practical amateur purposes. Many professionals deal with a complete end-to-end transmission system, while most amateurs can control only one end of the transmission path.

Henry, WA0GOZ wrote:
When making a J-pole antenna, does the shield go to the stub or to the long length?"

My experience includes clips on the coax to find the best antenna match. It is easy in this situation to reverse connections to see if you can tell a difference.

The 19th edition of the ARRL Antenna Book has a Super-J in which the braid connects to the long stick (p.16-25). Arnold B. Bailey does the same in his J-Pole Antenna example. Unless experiment proved the reverse choice better, I`d "follow suit".

Source record: 137620

I have a multiband (160M-10M) dipole on a 100 ft. RG-8X feedline.

On 80 meters, my radio's meter and my tuner's meter show that I have the rig tuned to SWR=1.0 and 10 watts power.

I put a Radio Shack digital meter after the tuner and before the feed line. It shows SWR=12.0 and power=24 watts. The SWR formula I know indicates that reflected power is 71% of forward power. What power is actually being radiated? Is this an OK situation?

Any antenna is better then no antenna! I would hate to read what these old cronies would say if I talked about how I use a 40m hamstick with my LDG auto tuner on my bicycle. Old cronies: say what you want about how bad this setup is, 20m qrp bike moble does work! Read my logbook!
I think the setup you discribe would work, however, you may want to try useing more the one wire and feed with coax. Is this for an appartment setup? I can help a little with that subject.
You could use two hamsticks together in a dipole form with the ladderline, just beware, two 75m hamsticks can get costly.

I went to Hobby Lobby and got a large spool of copper tape used for stained glass crafts. It costs about $4 for about 40ft. Just cut to fit and tape it up onto an eve or something. then paint over it Mine works really good for local stuff.
"Pendrgn2002" <pendrgn2002@aol.com> wrote in message news:20020730082408.10144.00000251@mb-mr.aol.com...

DPH <rally2xs@compuserve.com> wrote in message

This is all getting a bit silly . To really determine what is the BEST antenna
one must know what specification one has to meet to achieve or better it .

To say what is the BEST antenna one has to know in some order what the user is looking for i.e. what they must have as in advantages and also the disadvantages that some bring with them on the debit side.

Now many are opting for a G5RV or a long horizontal wire which in the majority of cases cannot be used by the average ham. His garden or yard is not large enough for it so they would be hard put to call it the BEST antenna.
In the same line of thought a list of ideal characteristics must be developed
so that one who strives for a BETTER antenna knows where to focus his thoughts.

I for one value multi frequency characteristics in the HF area where I can also tune outside of the amateur bands which is what the I.R. antennas do.
As an engineer I also look for little complexity which is where the I.R. antenna fails. At the same time I want the gain that goes with aperture or the air space available and rotatability and many antennas fail in this area to, and yet the amateur always cries for the max gain possible
in the final analysis.
So what is the best antenna and why? I have given the characteristics that I desire so I use a antenna that provides all or most of those characterics.
If somebody has a large garden or yard with two pink poles that allowes him to sling a wire inbetween with the minimum of effort then to his mind it is the best antenna, even tho he could build a antenna that meets my desired specs which can also can be verified by using first principles rather than a bit of apparent hokem that we see with the E/H antennas.

So I invite all hams to decide what 'they' desire from say a 'multi frequency'
antenna and use this criteria to determine the BEST antenna as I have done by listing what I desire regardless of availability and making one that meets those criteria with a minimum of complexity i.e those listed above.
As Reg would say.... Get back to first principles if you want to

search for the new or as in most cases novel innovations that use existing laws to satisfy your needs. For those who lack the understanding of first principles by all means
go to present day designs, (best source being the ARRL publications) but you must list your requirements first to aid in that search for the BEST antenna as only in the 'new' are we going to get the BEST 'overall' antenna. Some say you can't have everything but that is not true, humans have met their needs time and time again so why cannot hams strive for everything ? As one said ,'if we didn't innovate we would still live in caves !'
Have a great week end

Source record: 137631

Hi Henry

If it's a single band J-Pole, connect the feed to the stub and the shield to the vertical. On a multi-band J-Pole the feed should go to the vertical and the shield to the stub.

Although it works basically the same, either way it's connected, there are minor advantages on single band J-Poles by feeding the stub. One is reduced RF on the feedline, if you didn't enclose it inside the pipe, the other is less static discharge noise from the antenna itself. Placing 3 short non-resonant wires around the top cap of the vertical will also reduce the noise an equivalent amount.

Hi Art,

Lazy? You accepted the math above without challenge (which, according to G6AUC, and confirmed, appears to be wrong), without going to the books to validate, without review at the bench, without discussion of basics, without....

You are quicker to characterize the readership of this group with:
>We are so lazy
than to test the technical content. -Speak for yourself- These posts exhibit classic examples from two sources how the snobbism of populist science (sic) mocks established learning for apparent failure and then fails in its own sub-standard of performance.

Like fractal/cfa/eh science, populist science (sic all around) can be recognized by the sly contempt held for the reader:
>>The foregoing is beautifully simple and is exact, easily understood by
>>anyone who can do arithmetic.
(now an ironic statement) or by inflamatory proclamation (denotes a weak technical statement being braced up by homilies and innuendo):
>>Regurgitation of the old stuff by plagiarists
which, when attended by math that is obviously derived from other's work without ascription - truly plagiaristic (and worse yet, rife with error) is hypocrisy in its most obvious form.

Any apologies?

From: Fredrik Olofsson <574olofsson@telia.com>
Message-ID: <Due29.18421$p56.5948071@newsb.telia.net>
Source record: 137634

My simulating experience allows little conclusions, except that with a long radial (in the same direction) it might be worthwhile to share.

(Thought) experimental setup

Construction

1) Take a 14 meter long wire, a slightly longer rope and two pulleys.
2) Attach both ends of the wire to the other ends of the rope in some way
3) Attach the rope-wire "ring" to the pulleys so it can run between them.
4) Install one pulley in a tree at 5 m height and fasten the other to a pole at 1 m height
5) Run a coax from the shack to the pole and find some means to achieve electrical contact from coax center to the wire running at the pulley, and let the coax shield connect to a long radial.

Tuning procedure for frequency f

1) Search for the best SWR <= 3:1 in the vicinity of 214 / f meters wire length by
sliding the rope and wire
2) Mark this spot on the wire

Operating is straightforward: Find the right spot on the wire and make an electrical connection.

/Fredrik

Ken, First I would have a relook at the Radio shack SWR meter. I
bought quite a few of those for checking SWR at the antenna plus the
use of a peep hole camera.
Check it against a known reliable meter at different power levels to
see if the digital one needs recalibrating.
If you do not know how to recalibrate get in touch with me and I will
see if I can find the instructions

I would imagine that the first requirement would be to obtain a preamp
that will achieve low noise levels across the frequency range of
225-400 Mhz rather than
putting emphasis on gain and also using a standard ham antenna used
for 440.
Combinations of pre amp and antenna I expect are available
commercially.
Hopefully somebody else can help you with the extended frequency range
you speak of in question (b)as I imagine it could be difficult to
obtain a low noise amplifier to cover satisfactoraly the extended
frequency range spoken of.
Good luck

Most interesting. I had no idea that the J pole had been around since 1915. Or that they had the ability to measure antenna gain with that precision back then. Live and learn.

The gain he quotes for a J pole is in disagreement with modern modeling programs, which are operating well within their capabilities in analyzing that sort of antenna. On that basis, and considering the 1915 source of his data, I'm prone to believe he's wrong.

Gene, you make an excellent point with the above.The professional in
most cases
is given a task to which he must supply a workable solution. Unlike
the weather man or meterolist who have the luxury of getting it right
half the time
he as an engineer must get it right the first time.
This requires attention to first principles rather than hunches to
ensure we make something that meets the object required by the
employer. In many cases new ideas come to the fore but unless they are
relevent to the field or task at hand they are filed or placed on the
back burner if even tho they may be valid and meet basic first
principles.
In general the ham is a hobbyist who instead of examining what the
task is at hand, can afford to be wrong or can afford to fall back to
the books to get any antenna, because he has not a definable task to
solve .But then it is just a hobby that attracts people of many
background many of which are willingly to experiment without the rules
in the hope they find the Eldorado or buy a lottery ticket with the
same odds for success.

There is always the option of a pair of TUTs repeaters, any reasonable
copper pair will do betweent them.

The Radio Shack meter gets the dummy load SWR right. I could try a few readings on the dipole without the tuner and compare them with my radio's SWR meter. I think I did that once before and the two were in the same ball park (e.g. RS SWR 1.4 vs 1.2 per radio; RS power 9.6 watts vs. 10 watts per radio). In fact, tonight I will move the RS meter between the radio and the tuner and check it again.

However, if you have the info on calibration, I would appreciate it. The user manual doesn't cover it and makes it sound like a big operation.

I am thinking that with the 100' feed line (plus another 12 ft for various additions) I am getting close to 1/2 the wavelength on 80M. Maybe I am just getting a big standing wave in the coax, which is starting to resonate in the first (zeroth?) mode. Would a ferrite toroid choke in the middle help? Or would it choke off my signal and melt the PVC cover? Should I care what is happening if my tuner gets me to SWR=1.0? At full legal power, would I overload my tuner because of the 2.4X power amplification?

Roy Lewallen wrote:
"---I`m prone to believe he`s wrong."

I`m surprised that Bailey shows a 2 db loss as compared with a 1/2-wave dipole. The J-pole is a 1/2-wave dipole. The 1/4-wave stub is just a matching device.

Even so, the circle representing the horizontal pattern is drawn 2 db smaller than those for 9 other vertical antennas. The data sheet also says gain: -2dBd. So the exceptional J-pole is conspicuous. I would only speculate that Bailey considered it proper to repeat data reported by Zennek and Seelig which they published in 1915.

I`m prone to agree with Roy that Bailey is wrong in this instance simply because I see no place to develop 2 db loss if the same care is taken with the J-pole as with the other vertical antennas. There may be some other mistake lurking in "TV and Other Receiving Antennas", but I`d still wager that they are few and far between because the author knew his subject. This 1950 book is a first edition.

Best regards, Richard Harrison, KB5WZI

I think I just said: "The J-pole is a 1/2-wave dipole." The J-pole is not a doublet or dipole. It is end-fed. But the method of feed has little to do with antenna radiation characteristics in this case.

The J-pole antenna is a 1/2-wave radiator and has essentially the same characteristics as a 1/2-wave dipole. My motor is sometimes not running when I shift to drive.

Best regards, Richard Harrison, KB5WZI

2106. Coax Length for Fixed Frequency Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-01 21:07:14 UTC
From: Al <aburzynski@swri.nojunk.edu>
Message-ID: <ukj8o37iv0n15b@corp.supernews.com>
Source record: 137647

I plan to build a simple dipole and operate on 14.070MHz only (yes, I like PSK) using about 30 watts max. In an article on balanced systems in

http://www.moonraker.com.au/techni.feeders.htm

the author talks about the transmission line approaching an electrical 1/4 wave length. I do not understand if this is desirable or undesirable. In other words should my feedline be a multiple of 1/4 wave or 1/2 wave if I'm going to use it on one frequency only? Or is all of this really quite unnecessary and should I just use any reasonable length of coax?

A second question. This antenna will be about 4 feet above the eave of my house, running the full length of the eave. The underside of the eave is covered with vinyl coated aluminum. Will the nearness of the antenna to this aluminum covered eave be a serious problem?

I'm not going to ask anything about the balun I plan to use. I don't want to start any wars just yet.

Thank you.

Hi Reg,
Don't be so quick to change what you had originally. Why should
antenna gain at the ends of the path be given by the term Gt/Gr? The
transmit antenna contributes gain and the receive antenna also
contributes gain. 73,
Bill N3WK

2108. Re: Computing power from SWR

Hi Ken,

Thoughts below...

> On 80 meters, my radio's meter and my tuner's meter show that I have
> the rig tuned to SWR=1.0 and 10 watts power.

Ok, so far so good.

>
> I put a Radio Shack digital meter after the tuner and before the feed
> line. It shows SWR=12.0 and power=24 watts.

Problem. The meter is showing the total of the original
forward power and the reflected power. The power meter
will only be close to accurate if it is looking into its design
impedance of 50 ohms. Putting a meter after the tuner
is pointless, as it will not work correctly.

The tuner will provide a match to the transmitter and will
take the input power and apply it to the load. How much
of that is actually radiated depend on several factors, the most
important of which is the loss in the coax feed. This loss will
be fairly high, depending what the actual load impedance is
and the type of coax used. With a 12:1 SWR on the coax, I would expect
losses to be fairly high. Of your original 10 watts, some is
being lost in the coax.

How much? Probably not enough to lose sleep over.

The SWR formula I know
> indicates that reflected power is 71% of forward power. What power is
> actually being radiated? Is this an OK situation?
>

Ken, as long as the tuner provides a match, and does not
arc, you are OK. Personally, I would ditch the coax and
feed the antenna with ladder line. The ladder line will
have very low loss even at high values of SWR. This
will ensure that more of those ten watts will be radiated
instead of being wasted in heating up the coax.

Cheaper too!

Just run any length of coax you want to . Just make sure it will reach from the antenna to the rig..hihi..

If the aluminum is running that near the antenna for the whole (or biggest part of) length it will probably have some effect on the antenna. Just how much is not known . Try to move it somewhere else.

Forget the balun and if you really want to at the feedpoint you can wrap the coax in a coil of about 6 turns around 6 inches in diameter.

I would expect maybe dipole-like gain. What did you get? Its big
claim to fame is bandwidth. It should work fairly well just because
it is big. But, maybe not.

If one looks at designing a dipole that gives more gain than the standard dipole
then one has to incorporate a quasi collinear design. If we want a 'variable frequency design we must then design to accommodate the extreme space provided for our antenna . Cecil (CAM)has shown that you can get multi BAND use by the provision of variable length feeder lines or their equal in a similar fashion
of the Zepp family where collinear gains are realised by using the feed line
to provide a 'dead zone' at the center which provides for side lobes if the radiation is not exactly cancelled. Designs that are based on radiation cancellation are not good candidates for multi frequency use because of it's reliance on the feed line. The grid dip meter operates by mixing two resonant frequencies to where the current flow dips to near zero, a situation that produce ZERO radiation.So if we have two resonant circuits that are placed
close together to produce a portion of zero current flow and a consequential
lack of radiation. If we combine into one circuit for maximum coupling and use a conventional 20 meter dipole as the 'other' resonant circuit in conjunction with a variable loop antenna we start to aproach a collinear dipole antenna IF we drive the 20 meter portion of the dipole instead of the loop.
The basics of the above was shown in the ARRL Antenna book 17th edition as the the 'Resonance Breaker' and in the Radcom of the UK, both in the year '79 and regurgitated ever since. In later editions of the ARRL book the circular
loop design was transformed into an oblong shape when it was realised that maximum efficiency should give way to maximum coupling. For feeding purposes
one can intuitively place at the extremes of what now appears as a parallel circuit around the center, so that the 20 meter dipole is being driven .
Fortunatly this fits in with the delta match design which provides for reducing a high impedance into a more manageable impedance value. With this design
and the addition of a 4:1 balun acceptable SWR values can be achieved over the whole frequency range Of 20 thru 10. And above ten if one can live with multi rotatable radiation lobes and gaps in continual frequequency use. For areas below 20 meters I was fortunate that the 200b feet of coax that I used gave me use of both 40 and 80 where the coax came into play and where the 'antenna' moved from a
bi-directional antenna to a 'flat top' vertical. I will leave it to any interested reader to compare advantages and disadvantages to his

own list of desirables to see if this combination loop/dipole antenna meets their priorities and needs. This antenna is free from any restrictions in use as all relavent patents of mine have now been abandoned.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D49C023.8060909@eznec.com>
Source record: 137659

I was questioning your earlier statement that:

>Both scenarios often call for directive antennas. The J-pole has no
>discrimination at any azimuth and has a little less gain than a dipole,
>ground-plane, or coaxial antenna, typically -2dBd, according to Arnold
>B. Bailey who holds U.S. Patent 2184729, 1939, on the coaxial antenna.

which says that the J-Pole typically has 2 dB less gain than a dipole, according to Bailey. I maintain that Bailey is wrong about this (unless he's comparing a J-pole with coupled feedline to a vertical dipole with decoupled feedline). Do you agree, or do you believe Bailey?

Such antennas, with good gain, small size, and very broad bandwidth, do exist.

Unfortunately I am not aware of availability to the amateur radio service nor SWL'ers. An unfortunate restriction based on the times we live in...

I agree that the equation needs to be this, but I'd be interested
to know if you could resolve an apparent paradox that seems to exist
with this equation.

If I have two parallel 1/2 Lambda dipoles, with gain Gd, in free space
separated by distance D, one of which is attached to a transmitter putting
power Ptd into the antenna, I can use the equation to compute the power
delivered to a receiver matched to the other dipole, Prd.

Now suppose I instead consider to parallel 1/4 Lambda monopoles on
a perfect ground plane, operating at the same frequency and separated
by the same distance as the dipoles. I expect to be able to predict
the behaviour of the monopoles from the behaviour of the dipoles. To
reproduce the same field as existed between the dipoles (only with
half the total energy since it is restricted to a hemisphere instead
of a sphere) I need to produce the same current distribution in the
transmitting monopole, but since the feed point impedance for the
monopole is half the dipole this requires only half the power. This
means that

Ptm = Ptd / 2

Since I'm producing the same free-space field with half the power the
gain of the monopole is twice that of the dipole, i.e.

Gm = Gd * 2

Since the field is the same at the receiving monopole as it was for
the receiving dipole, I expect the same current distribution to be
induced at the monopole as the dipole. Since the feedpoint impedance

of the monopole is half that of the dipole, however, the power delivered to a matched receiver by this current will be half, i.e.

Prm = Prd / 2

This seems correct. The free-space field and the currents in the transmitting and receiving antennas are the same for the dipoles and monopoles, and to achieve this the powers into the transmitting antenna, out of the receiving antenna and propagated away into free space (of which there is half as much in the monopole case) by the field are all halved. If you believe that monopoles over perfect ground have an analogy to dipoles in free space it seems this must be true.

It isn't true according to your equation, however. If I substitute

Ptm = Ptd / 2
Gm = Gd * 2

into the equation I get

Prm = Prd * 2

That is, your (simple) equation says I'll get 4 times more power out of the receiving monopole as I would expect from consideration of the (even simpler) monopole/dipole analogy. One of these has to be incorrect.

As another data point, there was a discussion here a few weeks ago about a paper which compared NEC computations to that equation and also found that the equation overestimated the receiver power in the monopole-over-ground case by a factor of 4 compared to NEC.

I believe that your field strength meter equation has a greater dependence on the receiving antenna geometry than can be parameterized by a single gain value, and that the equation in the text books really only works for dipole receiving antennas. I could easily be wrong, though.

Richard what I liked was the 'back to basics' aproach and to be honest I do not understand the formula that Reg presented and nor do I desire to.
But frankly Richard you are getting to be a pain in the arse. You are not an expert with respect to antennas and frankly the idea that anything must be validated by you I find preposterous. Your career aparently is that of a weather man or meteroligist that looks after a herd of iterations, accepts with satisfaction the multi weather forcasts that are generaly wrong and tries to speak as Shakespeare would. This is not generally a sign of a good engneer let alone a antenna designer which both you and I are not, where it is common what is right first time. The idea of you criticizing me is tantamount to you giving the weather forcast for the previous day. True I may be ripe for attack because of my writing but that doesn't make me an idiot. Try talking slowly and loudly to a Canadian in Quebec as if he was an imbecile first time around and you will get a physical surprise for your arrogance. And no, I will not try to get along with you by accepting the blame or turning the other cheek. I am sure you can provide serious comment with respect to antennas but you cannot go the extra mile as a quasi antenna expert as all will see thru you as just 'mouth and trouser.'
To boot, if you think your acid comments will compel me to drop the antenna idea
you can forget it I have a bit more spine than you think. So lighten up, have a change in attitude or withdraw from the thread and go and play with your itterations or other animals that you apparently cavort with.

Your friend the Englishman
Art KB9MZ....XG and proud of it.

> indicates that reflected power is 71% of forward power. What power is
> actually being radiated? Is this an OK situation?

If power figure you quote is the forward power and the instrument is correct for both power reading and VSWR (big assumption!); you have 24 watts travelling toward the antenna at the tuner end of the feedline; about 7 watts net power into the feeder at the tuner; VSWR at the antenna is around 50; and about 1.6W (or about 16% of the rated transmitter output) absorbed by the antenna.

Looks like the tuner losses and line losses (exacerbated by high VSWR) are consuming 84% of your output power. Of course, this doesn't consider antenna losses.

Despite the sensitivity to instrument error, the underlying message is that it is not working well, and bears serious investigation.

The tuner meter didn't tell us much at all, did it! It shouldn't give you any comfort.

Can you please explain this last sentence further? The 'dead zone' is at the center of what -- the antenna, the antenna pattern? How does a 'dead zone' create side lobes? The radiation from what is being cancelled?

> Designs that are based on
> radiation cancellation are not good candidates for multi frequency use
> because of it's reliance on the feed line.

What kinds of antennas are "based on" radiation cancellation? Can you give a few examples? The fields from the elements in a W8JK partially or fully cancel in all directions -- that is, they don't completely reinforce in any direction. Yet it's a good broadband design because it maintains its pattern over quite a wide frequency range. Is this the "cancellation" you're talking about, and what does it have to do with feedlines?

> The grid dip meter operates
> by mixing two resonant frequencies to where the current flow dips to

The grid dip meters I've seen oscillate at only a single frequency. Although the grid current dips when there's maximum coupling to another circuit, the meter's coil certainly continues to radiate. Where is this "portion of zero current flow" you mention?

> If we combine into one circuit for maximum coupling

> The basics of the above was shown in the ARRL Antenna book 17th
> edition as the the 'Resonance Breaker' and in the Radcom of the UK,
> both in the year '79 and regurgitated ever since.

Unless I'm mistaken, a "resonance breaker" resembles a gamma match. But what it does is *prevent* current from flowing beyond the "breaker" section. In the "breaker" section itself, the currents on the two parallel wires are nearly equal and out of phase (although they can be large), so little net radiation takes place. This method is used in the AM broadcast industry to de-resonate parasitic conductors to prevent pattern distortion. In what way does this resemble a collinear dipole, which has substantial current along the whole length?

> In later editions of

In what way does the coax "come into play"? Do you mean it's radiating? If so, what makes it radiate on 40 and 80 but not on 20 and above?

That's really a great insight. You still have the potential problem of getting an impedance sufficiently larger than the common mode impedancance. But it should eliminate the potential loss due to differential mode coupling between the twinlead and the core. Neat idea.

Lee at Cushcraft called me today and took my order. The antenna is out of production, but, I feel satisfied that my parts are on order and I will get then at a fair price in reasonable time.

Lesson Learned:
1) Don't bother ordering parts via the Cushcraft web site.
2) Use the telephone to call technical service.
3) Failing that, keep telephoning and leave a message with your telephone number.

Two other people responded to this thread indicating they also had difficulties ordering parts from the web site. They suggested telephoning or using a Cushcraft dealer.

Dear OM,

I am not here to judge things not related to antenna. but i do agree
with Reg that ARRL antenna book(s) need to be updated largely. why?
Its obvious that there is a tremendious gap in basics presented here on this
NG, by you gurus like Roy, Reg, etc. I am a new ham with no EE background but
with basic logic i could understand what Reg or Roy exemplify while
reading ARRL books i fail to follow.

With as huge a book as the ARRL antenna bible, many basic
underlying concepts are missing. yes reading chapters
after chapters and i cannot find the formula for a field meter.
or when i read about the lightning part, i almost learn nothing yet reading
Richard Harrison or Tom's posts here i learn a lot.

I thank Reg for his wonderful programs. not only are they
free but they are of the highest ingenious quality. Reading the brief
"introduction" part in the respective program alone has taught me a
lot more than what the ARRL bible conveys. the programs may not be
100% precise but they are educational at its best.

Source record: 137578

>What happens to all that "choked" RF?<

Depends. Ideally, the blocking impedence of the choke looks high enough so that virtually all of the current ends up on the low impedance antenna leg rather than on the cable. If the blocking impedance isn't high enough, and if the blocking component is more resistive than reactive, the beads will heat up like resistors. However, the idea isn't to have the beads soak up the power, the idea is to make the path so "unattractive" that the beads don't have to soak up anything.

Al,
Unless you need a linear transformer for
impedance matchig, or 'phasing', there isn't
any particular reason to use a multiple 1/4
wave feed line. As long as the feed line is
long enought to reach between antenna and radio,
it should work just fine.
Anything close to an antenna will affect it's
performance or characteristics. How it will be
affected is a good question. It would be 'better'
if you could move the antenna further from the
metal in the eaves, but if that isn't possible,
it really shouldn't be ~that~ much of a problem.
Since you don't want to bring us the subject
of a balun, I won't either...

Think of how many hams there are, the kinds of antennas they use, and the purposes they use them for. Also consider the range of experience, knowledge, and math ability they represent. Then try to think of what you'd include in the Antenna Book that would satisfy the largest number of them. No matter what you include or exclude, you'll get a large number of gripers and armchair quarterbacks complaining about it and bragging about how they could do better. Oh, I forgot to mention -- you've got to find capable authors willing to work for next to nothing, so you can sell it for a fraction of the cost of most textbooks -- otherwise most hams wouldn't buy it.

You think it ought to be updated more often? Get out your word processor and start writing. Or would you rather quadruple your dues or pay $150 a copy so the ARRL could hire some professional writers?

If you're interested in fundamental antenna theory, there are plenty of good textbooks out there. Get one and read it. But you'll have a hard time finding good and reasonably accurate information that's of practical everyday use to a large number of amateurs, anywhere except the ARRL Antenna Book. If the Antenna Book replaced its contents with the same information that's already available in numerous texts, then where would you go to get the information that's in the Antenna Book now?

I've written most of a chapter of the ARRL Antenna Book. How 'bout somebody else take a turn? But I realize it's so much easier just to bellyache about what "they" aren't doing to suit you.

And Reg, they'll happily accept manuscripts from Limeys -- you don't have to be an ARRL member. Shucks, you don't even need to like Americans. Here's your chance to do something constructive, and show a thing or two to that world of old wives, gurus, fools, and incompetents that people your world.

Source record: 137587

Roy Lewallen wrote:
"I was questioning your earlier statement that:
----which says that the J-pole typically has 2 dB less gain than a dipole."

Let me be clear, I was wrong. Simple logic says a 1/2-wave radiator is a 1/2-wave radiator. If done right, how the 1/2-wave radiator is fed won`t affect its efficiency. So, a J-pole should have 0dBd gain.

Why I erred is unimportant. I was just careless and non-critical of material I passed along. I apologize. I will try to give more thought to my responses to avoid future errors.

2 db loss is unimportant to the point I intended to make. The question was the suitability of a non-directional antenna for FM reception in a city like NY,NY and in a rural hilly area. My reply was that the J-pole was probably not the best choice.

The reason the J-pole is not likely the best choice in either location:
The city is usually rife wirth multipath signals.
The hilly rural area has obstacles and distance from senders in the city.
Directive antennas are useful in both city and rural areas to overcome common reception problems, even when an attenuator may be needed to avoid signal overload.
The J-pole is a non-directional antenna. It is susceptible to multipath signals which may be found in town and in the country. The J-pole has no gain which distance from senders may require in the rural setting. A directive antenna is often a better choice. When signals from many directions are to be received, the directive antenna can be used with a rotator.

Best regards, Richard Harrison, KB5WZI

I have to strongly agree. I generally find the writing in the ARRL book to be excellent (though the cross referencing could be better), and I've noticed a marked improvement over the last, say, 20 years or so. When I want to understand something that's puzzling me related to antennas I'll pick up the "Book" before I'll go get my copy of Stratton or Jackson. But they're there should I want to go deep (and risk drowning).

What is a "low impedance antenna leg" and how do you measure the impedance
provided such leg exists?

Tom Donaly KA6RUH

2150. The Radio Path From Tx to Rx

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-02 07:00:37 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aidamk$f1f$1@venus.btinternet.com>
Source record: 137591

There was a surprising amount of interest and heat generated by the 3
'back-to-basics' equations in which a typo-error caused a little confusion.
Here they are again - hopefully error free - plus two more of lesser
interest.

==========

The following equations are exact. No approximations are involved.

D = straight line Tx-to-Rx distance, metres.
Pt = transmitter power output, watts.
Pr = receiver power input, watts.
Gt = gain of transmitting antenna rel. isotrope.
Gr = gain of receiving antenna rel. isotrope.
Lambda = wavelength, metres.
E' = Far-field field strength, volts/metre.
Pd = power-density, watts per square metre.
A = antenna aperture, square metres.

Equation 1.
========
Pr = Gr*Gt*Pt*Square(Lambda/4/Pi/D) watts.

Equation 2.
========
E' = Sqrt(30*Gt*Pt)/D volts/metre.

Equation 3.
========
E' = 4*Pi*Sqrt(30*Pr/Gr) volts/metre.

Equation 4.
========
Pd = Pt/4/Pi/Square(D) watts/square metre.

Equation 5
========
G = 4*Pi*A/Square(Lambda)

The power gain of an isotrope is 1.

==========

It is now necessary only to take into account efficiency of the antenna +
feeder + ground systems and losses in the ionosphere.

If you make it "unattractive" for unwanted currents to flow on the
outside of the feedline, all the current flows in the antenna instead.

Whenever you change something in the antenna-feedline setup, the RF
currents will always rearrange themselves to cope with the new
situation.

Pr = Gr*Gt*Pt*Square(Lambda/(4*Pi*D)) watts.

> Quickly, I'm curious where the "30" comes from (in terms of first
> principles) ?

For an isotropic radiator, the power density on a sphere of radius D
is going to be

Pt/(4*Pi*D*D).

For a non-isotropic radiator, we would get

Pt*Gt/(4*Pi*D*D) in a particular direction.

This has to be equal to E*E/Z0 where Z0 is the characteristic impedance
of free space, which is 120*Pi (if we take the speed of light as
3*10**8 m/s.)

So we get E*E/(120*Pi) = Gt * Pt /(4 * Pi * D*D), which reduces to the
second equation.

Harry (G6AUC).

Ah, "30" comes from "120" and "4" (both of which are famous 'first
principles' numbers).

Thanks !

Too true on both counts. I noticed military listed on the
applications list. Just what product does this buffoon (Buffoon
status determined by years of acting like a buffoon on the newsgroups,
proof is in the pudding, so to speak) make that meets mil.spec. or has
passed any military testing (US military only, no third world crap)???

Has anyone ever seen a company web page that touts the warnings it
supposedly has made to another company? News outlets do that but, I
can't ever remember any "real" companies doing that ;<}

The discone part of the antenna will, but with no gain. Now if the
vertical section is designed to operate in the marine band, the
results would be about the same as a vertical marine band antenna.

>
>(2) Has anyone tried the Antenna Warehouse "Super Discone" ($42)?
>http://users.cis.net/kingpop/Superdiscone.htm

A discone operates over a 10x frequency range. It appears from the
description that this one is designed for 120-1200 (they say 1300)
MHz. The vertical section is added for the lower frequencies..... it
will be similar to your basic, base loaded mobile antenna.

>
>(3) How do these things compare performancewise to homebrew J-Poles on

The jpole will be better than the discone for a single frequency.

> zone' create side lobes? The radiation from what is being cancelled?

To make two ponts of maximum current which are in phase the zepp uses
part of the dipole arrangement at its center PLUS a portion of the
feed line.
This center section also radiates together with some cancellation.
This radiation of the center portion of the antenna does not fully
cancel
and thus produces side lobes which is evident on the Zepp style
antenna where the energy supplied to form those side lobes are wasted
because they do not supply a useful purpose. The choice of the phrase
Dead zone is probably a poor one which I tried to emphasise by
enclosing it within '....'

> feedlines?
Well I do not have the over all knoweledge of antennas as you have so
I don't want to muddy up the waters by bring the W8JK into the
discussion but what I am trying to put emphasis on is that to obtain
the advantages of collinear gain
you have to use part of the feed line which complicates the priority
that I have
to have continual tuning as with the LOOP design that does not
incorporate the feed line. But bring up the point of cancellation is
important to my disscussion
because I was able to some what duplicate it by providing a section of
ZERO radiation instead of cancellation which provided side lobes as in
the ZEPP

Well I mentioned that possibly in error is to enlarge on the meaning
of the current drop to emphasis that when current drops to zero in a
circuit then there cannot be any radiation

> large), so little net radiation takes place.
No, I must respectfully disagree with you but I am guilty of using the
word 'Current' loosely as a ac 'current' will radiate where as a dc

current will not radiate. When dealing with mixing frequencies when we get to a point of zero frequency it does not negate the presence of dc current but only the absence of ac current (frequency)which radiates.

This method is used in the
> AM broadcast industry to de-resonate parasitic conductors to prevent
> pattern distortion. In what way does this resemble a collinear dipole,
> which has substantial current along the whole length?

To proved for the collinear effect which is the provision of two high current points in phase but separated in horizonal fachion to emulate two physically separated dipoles so one has to 'neutralise' the center portion as with the zepp.
In the method I show I am doing the same thing by providing for a 'no radiating
zone' by the mixture of two frequencies which can be varied by the use of a variable capacitor ala a LOOP which does not rely on a feeder or 'stub'

> In what way does the coax "come into play"? Do you mean it's radiating?
> If so, what makes it radiate on 40 and 80 but not on 20 and above?

Good point.

First I must add that I use 'perforated' 7/8 Andrew heliax and as yet I have been unable to locate any contribution of the perforations that could explain some things.

Before I tackled the remainder of my task which was to be able to use other lower frequences I checked out the veracity of the design so far by feeding the combination antenna with the feed line I use with other designs to feed antennas at the top of my 66 foot or so tower which

is some distance away from the house and to which the feed line is buried. The radiation pattern were similar to what I expected which was a dipole pattern without side lobes
and performed quite well as I rotated it. After this exercize I naturally
looked at the other frequencies I found that the SWR dipped in both of the
10 and 40 areas so I got on those bands which I am not particulary attracted to
ala bare foot and with a transmitter has one of those inbuilt tuners that are supposedly good for up to 3:1 I got on the air. I have no trouble in obtaining contacts with what was termed by others as a very good signal what ever that means. I also found that it appeared that I could vary the single frequency
by variation of the capacitor by tuning out TVI as well as generating it so the tuning capacitor still had an affect outside the 20-10 envelope.
So what greates the ability to operate outside the envelope ?
When I got down in the 7 and 3 Mhz area the use of the capacitor minimal as it was gradually lost its effect, I think I was using a capacitor with a range upto
around 200pFwith no consideration of particular high volages as needed withe loop.
With these observations I concluded that I had gyrated from the antenna alone as a radiator but to a SYSTEM that included the feed line where I had both horizontal and verticle radiation. I have a 1/2 acre buriud grid under the tower
which helps I presume.

Thus I came to the conclusion that when the capacitor was functional for changing frequency the combo antenna was radiating tho minimally to the point that when it didn't affect frequency change it bacame a system similar to a vertical where the antenna worked as a top hat. At this point I dropped the pursuit of TOTAL frequency response in the area tjho I continued to didle with this line of thought and did not pursue in practice. So yes, the feeder must be radiating which suggests SWR on the line but it was of no consequence to my transmitter.

Generally, that depends upon the degree of inefficiency the particular antenna. I practically expect close to 100% for antennas that are small fractions of a wavelength.

Would running a 250' insulated wire all over trees... going here and there at different angles work better than my 80 m dipole on 160 m?

The 80 m dipole is at 22' and that is about as high as I could get the wire.

Art Unwin wrote:
"The grid dip meter operates by mixing two resonant frequencies to where the current flow dips near zero, a situation that produces ZERO radiation."

Not to quibble, but I will present a different explanation of the dip meter`s operation using a solid-state dip meter as my example.

A dip meter can couple maximum energy into a circuit when that circuit is resonant at the oscillator frequency. At resonance, circuit impedance is reduced to only resistance as reactance is zero. Energy accepted from the dip oscillator rises sharply at resonance. My Heath HD-1250 samples the r-f voltage across the oscillator coil.

As energy taken from the dip coil rises, voltage across the coil dips and this is indicated on the internal r-f voltmeter of the dip meter.

A standing-wave antenna, such as a dipole, is a resonant antenna (circuit) when its reactances are equal in magnitude and opposite in type, that is they cancel. At resonance, only radiation and loss resistances remain to oppose current in the antenna. Resonant frequency excitation maximizes antenna current.

My Heath Instruction Manual advises checking for antenna resonance at a high-current (low-impedance) point in the antenna.

Best regards, Richard Harrison, KB5WZI

I don't follow.... coax notch filters use open/closed 1/4 (also work at other frequencies, such as corresponding 3/4 wave) wave stubs, usually thru T connectors, to null out specific frequencies by inverse phasing.

I wasn't asking about antennas OM:-) Notching has nothing to do with the antenna size, but the ability to phase- cancel using the stub.

==========

Never heard of Friis. Can't remember anybody else's name either. A few days ago somebody asked how to calculate field strength from receiver input volts using a 1/4-wave vertical. So I reversed the usual formula Pr = f(E') which has been in my tattered notebook for 40 or 50 years. It's been used at times to check whether anyone is exceeding the max power licence conditions.
==========

> Why is it seemingly ignored by the amateur?
==========

Because it doesn't appear in the ARRL Bible.
==========

> Many professionals deal with a complete end-to-end
> transmission system, while most amateurs can control only one end of the
> transmission path.
==========
Not so true anymore perhaps. How to do the calculations was well known to people like Heaviside 100 years back. They just did not write the formulae in the way I have done. Line transmission engineers had been using formulae for some years before then with the line characteristics in the place of the radio path. But their notebooks looked different to mine although they were probably no-more complicated.

Things really got going in the early 1930's when world-wide HF radio-telephone circuits blossomed. Radio-telephone circuit design became a routine matter. Oceanic and transcontinental telegraph cables now had a competitor. Design formulae were formalised in the engineering design and maintenance text books in the form we now see. Both ends of a radio circuit received equal consideration. Equipments and antennas were often identical.

A more common engineering way of describing a complete radio circuit is in terms of decibels. But I think the sight of equations in algebraic form is far more informative about what is really happening.

These days amateurs are concerned with both ends in such matters as setting up VHF repeaters. It was a fellow doing field strength measurements who raised the field strength question. He had searched high and low without result. So it was convenient to use the formula to introduce the subject of bringing amateur radio publications up to date. Then the non-existent errors began !

Hi Frank,

More topics, as has been pointed out, often leaves out MORE topics.
Or at least that is the perception of those whose champion was left
out in the last draft.

There is a world more variability in design in the SHF spectrum. The
scale of construction allows for more complexity. This same
complexity is construction overload at HF.

In HF design, rarely do you get into geometries beyond half wavelength
in overall dimension. When you do, it comes as consequence of an
opportunistic low band antenna. That is, using your 40M dipole at
10M.

If you had to buy one book, the ARRL's is as good as any; and quite
possibly much better than most. ALL texts have their problems, so it
serves no purpose to criticize the ARRL against a "higher standard."

The first book I bought on antennas, was from a bookseller in Frisco
where I was stationed 30 odd years ago. "Electronic and Radio
Engineering," Frederick Terman. This is not strictly an antenna book.
Rather, it is a comprehensive work on the mechanics of radio
engineering. It is not unusual to find this work offered in this
group as a reference to answer some technical criticism.

This is available at:
http://www.alibris.com/

for less than $20

http://www.amazon.com
for around $20

I find alibris very much better with rare or obscure titles; the example title above reveals alibris is ready to ship at $12 where amazon will hold your order at $20 for up to 8 weeks.

>. . .

Resonant frequeny excitation maximizes antenna current only if the antenna is driven with a constant impedance source. For a given applied power, resonance has no bearing on the magnitude of antenna current -- it's a function only of the feedpoint resistance (I = P/R^2). If you use a matching device and adjust it so your rig can deliver full power to the antenna, antenna resonance won't make any difference in determining the antenna current.

We don't follow you either. Your original post said:

"Wondering what kind of attenuation you can practically expect at HF."

Note than you did not describe anything of the configuration, the
frequency range, the method of construction, the allowable insertion
loss, etc.

So, based on the parameters you provided, the answer is 53.271 dB.

You're welcome.

==========

The equations are exact. They apply to all antennas.

It is necessary of course to insert the correct value of antenna gain,
taking into account radiating efficiency of a system.

Check into the antenna gain of a vertical 1/4-wave antenna above a perfect
ground relative to an isotrope.

Yours, Reg,

Roy Lewallen wrote:
"---its a function only of the matching resistance (I = P/R^2).

P = IR^2 ?
I think it`s P = I squared R.

But, I am determining the resonance of a 1/2-wavelength of wire by exciting it with a dip oscillator. A center-fed dipole has a short across its feed to determine this first resonance point. The short would be the high-current point and the place to be checking for resonance.

Best regards, Richard Harrison, KB5WZI

2189. Centerfed Dipole With Balun

Newsgroup: rec.radio.amateur.antenna

It seems you might have the wrong value of antenna gain relative to an
isotrope.

But it's not an important matter. The answer is still in the right
ball-park.

Regards Reg.

Unless you have a really long feedline I don't see where jumping between cable/ladder line is going to help you.
Ladder line certainly has less loss but this really only becomes a major factor when the SWR is high or the line is extremely long...or both.

Actually, the problem was well-posed, and K1TTT's own discussion on his links answered my question. The answer is that 25-30 dB of attenuation is common with HF using practical coax options for stub notch filters.

Thank you for your help anyway.

> Roy Lewallen, W7EL
I appreciate the discuusion guys but, the set up that I proposed is
where the other resonant circuit is driven that, is the 20 meter
element and not the loop resonant circuit. I may have used the example
improperly but my intent was to illustrate that the radiation can be
made to drop to zero at a varying length
at the center area of the 20 meter dipole in a way that most people
would understand as most hams have played with such an instrument and
have seen the meter 'drop' to zero . As I said, it may have been the
wrong aproach to prove a point where for a different reason the
current amplitude dropped to zero. The important thing to focus on is
that what changes in the current occurs it also
provides for collinear radiation which is extremely important.
I would readily accept a better explanation from those skilled in the
art of communication where I obviously fail but I am not the smartest
guy on the block.
Please keep looking at the antenna in it's entirety, I need to get rid
of this load I have imposed on myself. I am concerned that the thread
may drift away
or be side tracked to a point that all will lose patience with me. Roy
gets so many letters, e mails calls e.t.c that call on his generousity
and his kindness.
Tho I may not deserve it he is apparently again giving his time to me,
as he has done in the past to point out where I have slipped up. I
value his attention which is not to say I don't value others but
goodness, this means a lot to me.

Best regards to you Rich as you have also helped me out in the past
with your wise advice and knowledge.

For those who asked, the full calculator results used to source the
above analysis (excuse the format, pasting a html page doesn't work
elegantly in Netscape 4.x):

VSWR calculator results
10W tx on 3.6MHz, 100ft RG-8/X
Input values:
Parameter Value
Transmitter power output into matched load (W) 10
Forward power (W) 24
VSWR 12
Line loss to transmitter (dB) 0
Line loss to antenna (dB) 0.55
Antenna gain (dB) 0

Calculated values:
Parameter Value
Transmission efficiency (%) 24.09
Line loss due to VSWR (dB) 5.63
Effectiveness (%) 16.42
EIRP (W) 1.64

Parameter Transmitter Antenna
Fwd Power (W) 24.000 21.145
Ref Power (W) 17.183 19.503
Net Power (W) 6.817 1.642
VSWR 12.00 49.50
Return Loss (dB) 1.5 0.4
Voltage reflection coefficient (pu) 0.846 0.960
Power reflection coefficient (pu) 0.716 0.922

Well said, Roy!
Supplement with a copy of Kraus (Antennas) and one is ready to
understand. Even a first edition of Kraus is remarkably straight
forward in the first chapters. I know that his book is available in
several languages and, because of the lucid English, probably translates
in an effective manner.

To paraphrase a part of what Roy said: one can only place a finite
amount of information within a finite number of pages. The art is in
the selection.

Of course I read the header. Despite what you and Chirp think, the
question was not "well-posed" and is more oblivious than obvious.

Suppose we build a coaxial structure by hogging it out of a solid
block of coin silver?

That certainly meets the subject requirements doesn't it?

Or suppose we so lightly couple into the structure to maintain a high
Q that the off-resonance attenuation is 30 dB. That meets the subject
requirements too, doesn't it?

There are an infinite number of ways to implement this and an infinite
number of answers. 53.271 dB is one of the answers and is as good as
any other given the stated parameters.

And to think that this query was from a guy that proposes to sell crap
to the military.

I've seen 30-400 MHz, but they DO NOT have good gain at the low end. More like -15dBi. This is NOT "good gain".

The boys at JTRS are still trying to figure out how the heck they're going to cover 2MHz to 2GHz (or to 40GHz - crazy...).

Can you quote a National [or NATO] Stock Number (NSN) for the 'Antenna, Mobile, Miracle" to which you refer ? I'd like to order one to try it out...

Or is it....a 'secret' ?

A few days ago I spotted a used copy of _Antennas_, First Ed., at technical branch of Powell's book store in Portland. I see from their web site it's still available, and by mail order, priced at only $34. A bargain. You can find it at http://www.powells.com with a search, or you can paste the following link together and go directly to the right page:

http://www.powells.com/search/DTSearch/search?kw=&isbn=&author=kraus&publisher=&title=antennas&section=&class=all&binding=any&sort=by_title&sort2=by_author&store=all&perpage=25

Anyone really interested in antenna fundamentals at the level of understanding the equations we've seen here should have this book or a similar one.

Art Unwin wrote:
"If one looks at designing a dipole that gives more gain than the
standard dipole then one has to incorporate a quasi collinear design."

Art must have additional unstated limitations in mind because dipoles
can be arranged in several ways other than end-to-end to produce gain.

Mattress arrays make a broadside array of dipoles in the same plane. In
these dipoles are placed parallel to each other as well as end-to-end.

Dipoles can also be placed in front of and behind each other to give
more gain.

So, collinear is just one of several options to "give more gain than the
standard dipole".

Art mentions CAM`s feedline length selection plan for antenna matching.
I suspect Art has an antenna matching plan in mind to compete with the
CAM system. I gather it is a tuner directly at the antenna feedpoint
which consist of a tuned circuit employing a low-resistance loop and a
motor-driven capacitor.

I may be wrong because I get confused by talk of multiple reflectors,
etc.

If Art would parcel out one problem at a time we might give better
answers.

Best regards, Richard Harrison, KB5WZI

Reg, G4FGQ wrote:
"Line transmission engineers had been using for some years before then with the line characteristics in place of the radio path."

Yes, but these are quite different.

Before someone jumps to the wrong conclusion, it may be well to note that when you double the distance from a radio sender, you cut the signal voltage only in half no matter how large that doubled distance increment is! After a few iterations of this principle, doubling the distance is incresing the distance by many miles.

In the transmission line example, each mile of line extension extracts the same percentage loss on the remaining signal if it is the first mile or the millionth mile.

We now use radio over a path of millions of miles. Doubling this huge path length only increases total path attenuation by 6 db.

If cable loss is only one db per mile, one million miles of this cable has a path loss of one million db.

The formulas for radio and cable attenuations are distinctly different.

Best regards, Richard Harrison, KB5WZI

wrote:
>(see below)

Almost all of this goes right over my head. Why do you state that the
24 watt reading on the Radio Shack digital wattmeter is forward power?
I thought it was the total power and that it was the sum of the
forward and reflected power. Based on the simple formula for SWR that
I know, I get 14 watts forward and 10 watts reflected. Are you
possibly saying that of the 14 watts forward, no more than 4 of those
watts are making it out onto the antenna, with 10 watts reflected
back?

Assuming that under some simplified model my understanding is roughly
correct, what is causing the problem on this one band? SWR is much
lower on 160M and 40M using the same rig. If it is resonance in the
feedline, would it help to put a ferrite choke on the feedline (in
addition ot the one at the feedpoint)?

Making for more confusion, the antenna manufacturer says, Not to
worry: Even though there is some bouncing around in the feedline, a
decent signal will get out if the tuner says SWR=1.0. What principle
(principal?) is he travelling on?

Hi,

I'm looking to buy the following:

3) 18-26GHz waveguide to SMA FEMALE transitions
1) 18-26GHz waveguide directional coupler(3 or 10dB)
1) 26-40GHz waveguide directional coupler(3 or 10dB)
Coaxial cable good up to 40GHz (SMA to SMA)

If you have any of these lying around, or know were I can find these
email me your asking price to: wdizney@yahoo.com

Thanks for looking
Mike

I am sorry, I wasn't trying to confuse you.

> 24 watt reading on the Radio Shack digital wattmeter is forward power?

If the power reading was from a non-directional sensor, it is probably (almost certainly) only calibrated if the VSWR is 1 and means absolutely nothing otherwise.

I am not familiar with the instrument you have used, so you will need to check its documentation. You do need to understand what it measures, what it indicates, under what assumptions.

I assumed that since you offered it as a power reading, then it was from a directional wattmeter indicating forward power (ie the wave travelling towards the antenna).

Some of my calcs are based on that assumption (as I stated) and will be incorrect if that assumption is invalid.

Anyway, if the VSWR measurement was valid, then some of the calcs remain valid. The VSWR at the antenna is 50, and the transmission line loss is 6dB.

If you are thinking that the VSWR being 12 is tolerable, the VSWR of 100 ft of RG-8X on 3.6MHz with nothing connected to the far end (ie o/c) should be under 16. 2000 ft of the same line with nothing on the end will deliver a VSWR of better than 1.2, you need to consider the effect of cable loss on your measurements.

That sounds very much like a commercial approach (post sale).

His comments re "some bouncing around in the feedline" (interesting turn of phrase - I don't think it came from any radio texts) is suggesting that the intention is to operate the feedline at high VSWR and transformed to the the desired transmitter load with an antenna tuner (the so called tuned feeder configuration). We don't usually operate coax at high VSWR, because it is lossy even when matched, and when operated at high VSWR the losses are much higher. Rather, we would usually use open wire feeder of a low loss construction to operate with VSWR of two digits.

The principle is that you can afford high VSWR on the feeder if it has very low loss, whether it is coax or open wire feeder. It is just that at the frequencies that you are taking about, it is generally harder to get very low loss with coax.

The thing you have to try to discover, is whether the ugly VSWR and attendant cable losses are a sign of something faulty in implementation or a "design feature".

If the manufacturer is suggesting that you don't worry about losing a bit (not sure of how much now) of power in the antenna tuner, 75% of the power leaving the tuner being lost in the cable, what other compromises might exist in the multiband antenna (baluns, conductor, traps, earth etc). That is not to say that you won't get contacts, but we usually expect to getway better than half the transmitter rated power to the antenna.

There's way too many apples and oranges in the mix here.
First off, a cheapo Radio Shack meter (and many others) are simply
reading rectified voltage...both forward or reflected. You can take
Ohms Law and easily enough calculate watts as long as the impedance is
staying at a known value....that which the device is optimized for. Its
not a wattmeter, its a voltmeter and there's a big difference. Log10 vs
Log20 for starters.
But throw in any amount of mismatch and the whole computation goes to
heck because you don't know the Z to plug into the calculation. Neither
does the meter.
Such a meter is fine as long as you have a 'low' vswr. I wouldn't
bother trying to figure it out if it says something like 12:1.
Obviously the effort could be better spent working on the antenna.

Well, it was quite popular but was nevertheless discontinued by Radio
Shack. Information is still posted at:
http://www.radioshack.com/ProdSupport/DocumentDetail/DocumentDetailIndex.asp?URL=http://su
pport.radioshack.com/support_electronics/26476.htm

One is for sale on eBay and a pic of the box with photo is shown:
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=1370331557

I see nothing there (or in my user manual) that illuminates the issue.
Do your more expereinced eyes see something that gives a clue?

If indeed this instrument is telling me little that is useful, what
can I use to measure my signal strength? I have a field-strength
meter with a 6" solid rod antenna. Could I replace the rod with a
length of shielded cable having 6" of center conductor exposed at the
tip and use that on the end of a long stick (fishing rod) that I wave
over my dipole? Can I compare relative strength on 10M and 20M where
SWR is low without the tuner to that on 40-80-160?

I started out using a Yachtboy 400 a half mile away to measure signal
strength, but with 40-80-160, most of my signal is going up. I would
need to be in a balloon.

You guys are off the wall.

I don't know anything about any classified stuff. I don't seem to recall discussing anything like that.

The technology to do this type of bandwidth , with performance better than mentioned by a Canadian poster, exists, and such antennae exist. They are controlled distribution. Hams and SWL's can't get them. Its not a matter of whether they should or shouldn't; they simply can't. That's all there is to it--with respect to this venue.

This has nothing to do with anything else you guys mention. How you pose a happy, inventive guy as something else is fantastically amusing.

If there is a compelling reason why more factual information is needed, it can be discussed off line.

..and I believe that has already been said, so let others question your motivations. Its quite clear to me.

Five weeks ago, I requested that Steve Best, VE9SRB, engage in a scholarly public debate on the subject of fractal antennas.

The motivations for said debate are:

1) fractal antennas are rapidly becoming a major research interest of the professional and academic antenna community;

2) Steve Best has made a distinct point, in the last three years, to become an assiduous investigator into fractal antennas, indeed it has apparently become a dominant topic of his research interests, with well over a dozen public talks and publications;

3) through his work, Steve Best has posited himself as the key, and I believe the only published, criticiser of fractal antenna work, what some would discuss as an alleged 'debunker' .

4) IF fractal antennas have no value, and the hundreds of publications which report research investigations are incorrect, then the antenna community ethically requires a clear and timely presentation of the lack of such merits, in a way that settles the issue, and removes the facts from their mere interpretation (or misinterpretation). In other words, paradigm shifts should be resolve one way or the other. Historically, public, scholarly debates have accomplished such objectives;

5) Steve and I are friends and colleagues and it may be assumed that our motivations are purely scientific;

6) as founder of the field of fractal element antennas, and as the principle researcher and publisher of aspects of the paradigm, I am a logical choice to discuss the scientific aspects of fractal antennas and, indeed, Steve's periodical citing and public talks confirm this.

I must report that Steve Best has not responded to my offer to debate, at least to my knowledge. I look forward to his response.

Cordially,

Nathan 'Chip' Cohen N1IR

Wattmeters have a directional coupler that separates the forward conditions
from the reflected conditions. My Autek WM-1 indicates forward power and
SWR.

> Assuming that under some simplified model my understanding is roughly
> correct, what is causing the problem on this one band?

You're learning a lesson in what to believe from antenna manufacturers.
There's no such thing as a free lunch. Have you modeled the antenna?

> Making for more confusion, the antenna manufacturer says, Not to
> worry:

Of course the antenna manufacturer is not worried. He made his
exorbitant profit on a compromised antenna. Hope you enjoy QRP.

> Even though there is some bouncing around in the feedline, a
> decent signal will get out if the tuner says SWR=1.0. What principle
> (principal?) is he travelling on?

The power delivered to the load is forward power minus reflected power.
If at the input of the tuner you have 10 watts forward and zero watts
reflected and at the output of the tuner you have 24 watts forward and
17 watts reflected (assuming those figures are accurate), there is 7 watts
delivered to the transmission line and the tuner is dissipating 3 watts.
Subtract your transmission line losses and you will know the power being
delivered to the antenna.

But just because you can obtain a match with an antenna tuner is no
guarantee that "a decent signal will get out". Of course, the antenna
manufacturer has an entirely different definition of "decent" than
you or I do.

Here is Steve's response from last time, just to jog your memory:
==========
Steve wrote:

This is not intended to be a "debate", just a statement of opinion (or fact depending on your perspective). This is also very long - sorry. I won't post any other long statements on this subject.

The electromagnetic behavior and performance properties of a wire antenna are a function of the antenna's physical properties. These physical properties include the antenna's size (height, area, occupied volume, etc.), total wire length, geometry and wire diameter. If we conclude that the electromagnetic behavior and/or performance properties of an antenna are uniquely or primarily a function of one of these physical properties, we must also conclude that significantly modifying this one physical property will significantly modify the antenna's electromagnetic behavior and/or performance properties.

If we are to conclude that antennas having fractal geometry behave in a manner differently or better than antennas with a non-fractal or some arbitrary geometry, then we must fix all of the antenna's other physical properties (size, total wire length and wire diameter) and compare the electromagnetic behavior and performance properties of the fractal antenna with those of antennas having different geometries. This is something that none of the proponents of fractal geometry have done in the open literature.

Not one. Let's consider this further.

1) Cohen, in a series of Communications Quarterly articles, published the performance properties of the Minkowski Island fractal loop antenna. He demonstrated that with increasing fractal iteration these antennas exhibit a lower resonant frequency than a Euclidean (square or rectangular) loop of the same size (occupied area). He also demonstrated that in some regions of low frequency, the Minkowski Island fractal loops exhibit a higher radiation resistance than the Euclidean loop of the same size. Cohen concluded that the electromagnetic behavior and relative performance properties of the Minkowski Island fractal loops are primarily a function of the loops' fractal geometry. It is significant to note that two physical parameters of the antenna change with increasing fractal iteration. One is the antenna's geometry and the other is the antenna's total wire length. While the performance data presented by Cohen is mostly accurate, his conclusion is scientifically flawed because he is varying two of the antenna's physical properties but concludes that the antenna's electromagnetic behavior is primarily a function of only one of these physical property - its fractal geometry.

To scientifically validate his hypothesis, Cohen would have to compare the electromagnetic behavior and performance properties of the Minkowski Island fractal loop with those of other geometry loops having the same size, total wire length and wire diameter. He did not do this. When we compare the Minkowski Island loop with loops of differing geometries but otherwise having the same size, total wire length and wire diameter, it is evident that they exhibit very similar electromagnetic behavior and performance properties. In some cases, the arbitrarily shaped loops behave better than the fractal loop and

in some cases, the fractal loop behaves better than the arbitrarily shaped loop. In all of this however, the most significant fact to note is the following: when the total wire length of the arbitrarily shaped loops is adjusted such that their resonant frequency matches that of the Minkowski Island fractal loop, they have virtually identical radiation resistance and bandwidth. The resonant behavior of these loops is primarily a function of the loop size with respect to the resonant wavelength and the resonant properties of these loops are essentially the same independent of the differences in loops' geometry and total wire length.

2) Puente's work on the Koch fractal monopole suffers from the same scientific flaws as Cohen's work on the Minkowski Island loops. Puente describes the behavior and performance properties of the Koch fractal monopole as a function of increasing fractal iteration (increasing total wire length) and demonstrates that, when compared to a Euclidean (straight) monopole of the same height, the Koch fractal monopoles exhibit lower resonant frequency and increased radiation resistance in some regions of low frequency. Puente even goes as far as claiming that the complex shape of the Koch fractal curve enhances its radiation properties. Again, it is significant to note that Puente did not bother to compare the performance of the Koch fractal monopole with another monopole of different geometry but otherwise having the same physical properties (height, total wire length and wire diameter). For example, if we compare the Koch fractal monopole with a simple meander line monopole and normal mode helix of the same height and total wire length, we see that these simple geometries exhibit significantly lower resonant frequency and higher radiation resistance at low frequencies. As a function of height and total wire length, these simple structures are more effective radiators. Two points are even more significant: a) when the wire length of the meander line and normal mode helix antennas is shortened (while maintaining the same height) such that their resonant frequency matches that of the Koch fractal, they exhibit virtually identical radiation resistance and bandwidth. The resonant behavior of these monopole structures is primarily a function of their height with respect to the resonant wavelength and is essentially the same independent of the differences in geometry and total wire length. b) below the small antenna limit (ka < 0.5, k = 2pi/WL and a is the radius of a sphere encompassing the maximum dimension of the antenna), the radiation resistance of all these antennas converges to that of a Euclidean monopole of the same height.

3) One of the most profound and yet totally unsubstantiated conclusions regarding fractal antennas is that stated by Vinoy et al in an article titled "Hilbert Curve Fractal Antenna: A Small Resonant Antenna for VHF/UHF Applications" published in Microwave and Optical Technology Letters. In this article the authors claim "A fourth iterated fractal Hilbert curve geometry inscribed in a square of 7 cm is shown to result in a resonant frequency of 267 MHz, which is much lower than any other resonant antenna of similar size." How many

other resonant antennas of the same size did they compare with the Hilbert curve antenna? - zero, no even one. I fabricated a simple meander line antenna of the same size and total wire length as the Hilbert curve and it had a resonant frequency of 154 MHz.

The trend in the study of fractal wire antennas is to compare the fractal antenna with a simple Euclidean antenna and jump to a range of conclusions that are, for the most part, unsubstantiated. Comparing the fractal antennas with other geometry antennas of the same size, wire length and wire diameter provides clear evidence of this. It should be inherently obvious that increasing the wire length in a fixed size antenna lowers its resonant frequency and increases its radiation resistance over some range of low frequencies as compared to a straight Euclidean antenna. This behavior is simply not unique to antennas with fractal geometry. There is no inherent or unique benefit to a fractal geometry antenna compared to an antenna with virtually any other geometry. Fractal wire antennas do not behave in a unique manner nor do they behave in a manner significantly different than antennas with other geometries. This is especially true when the antennas are made to be resonant at the same frequency. It is interesting to note however, that in most cases, a self-similar fractal geometry is generally the least effective geometry in terms of lowering resonant frequency as a function of total wire length.

If the discussion turns to the concept that all bent wire geometries are "fractal" then the discussion gets even more ridiculous - we have assigned a new term to bent wire geometries but have learned nothing new about the fundamental behavior of antennas.

What would a couple of antenna gurus know about debating? Most of the
disagreements on this newsgroup usually end in sophomoric
name-calling and arguments over definitions. Besides, real debates
don't reveal the truth of the various arguments so much as they do
the level of sophistry of the participants.

Quite correct. My search was for collinear gains in the most simple of
cases as with the loop antenna which tho it meets my goal with respect
to frequency coverage it had too many disadvantages.

> Art mentions CAM`s feedline length selection plan for antenna matching.

Yes but that faied my goal with respect to complexity.

> I suspect Art has an antenna matching plan in mind to compete with the

You are right on the mark Richard.....it produces collinear gain
and does
have a variable capacitor to achieve variable frequency use
> I may be wrong because I get confused by talk of multiple reflectors,
> etc.

Multiple reflectors was part of another another thread and has no
technical connection

> If Art would parcel out one problem at a time we might give better
> answers.
>
> Best regards, Richard Harrison, KB5WZI

But Richard your respnses on this particular thread have articulated
my antenna

extremely well, much better than I could possibly do and I amm not conciously trying to confuse. I have previously supplied a picture of the actual antenna that was based on 10 meter use tho it used a 20 meter element which incidently is one driven reonant circuit. To this I have added a parallel circuit which contains a variable capacitor. To obtain maximum coupling to the loop (an oblong shape resonant circuit) I have merged them into one.
I also have chosen 20 meter portion(s) to be the reonant circuit to be the driver leaving the capacitor in the 'loop' to modify the radiation pattern to obtain a quasi collinear radiation pattern that varies with the use of a capacitor.
I realise that the concept is difficult to follow and is probably the reason why the concept has not been used for the last twenty odd years. Like most things
that are 'different' sometimes they are so obvious they are overlooked.
May be it would be better to model the antenna that I roughly drew, note how the
quasi collinear is formed with two max current points along its length and go forward from there. Apparently no one has used a antenna computor program to look at the simple wire diagram given because when this is done the 'penny drops'
Any way good job on the analysis. Now how do we explain it to others so all may share.
Best regards
Art KB9MZ

2237. Re: G5RV, coax/ladderline and remote tuner

Newsgroup: rec.radio.amateur.antenna

An alternative is :

Rig ---> coax jumper---> Tuner --->Coke Bottle Balun---> ladder line--> Antenna

The Coke Bottle Balun is 6-8 loops of coax wrapped around an empty 2 liter bottle of Coke (Pepsi if you prefer) with the ladder line connected to the coax coming off the bottle. I've used it with G5RVs and it keeps the RF out of the shack.

This way you can keep the tuner on your desk where it is reachable.

Good luck,

Bill, W4WNT

The light is starting to go on.

Seven watts out of ten I can live with. Maybe that is what the
manufacturer was talking about. At 100 watts into the tuner, or 600
(if I ever get my amp back from Yaesu) I am certainly not in QRP
territory. It is a compromise antenna, but it only cost $150 and I
can't fit anything more capable on my property. BTW, I don't think
this manufacturer is one of the irresponsible ones and most users get
good results with this antenna, although some don't.

What about my other question? WIll putting a ferrite toroid (with say
10 turns of the coax feedline) around 40 ft away from the feed point
quiet the feed line down and improve efficiency? I already have one
at the feedpoint. I say 40 ft. because the feedline radiates a great
deal at 40M also and I would like to use one toroid to kill two birds.
I would just try it but for the fact that it is a hairy job to unpull
and pull my feedline.

Just goes to show the total and utter lack of understanding of science
by Chirp.

Science is not a debate, it is the publication the methods, experiments,
and results such that they may be performed by others to validate them.

Steve Best provided science in his QEX article; Chirp provides rhetoric
in his post.

Such it has been all along with fractal antennas.

OOOOPS
what I am descibing is a single wire radiator not an array.

I failed earlier to note " a tuner directly at the feed point"
that is incorrect tho I personally use a balun here because of the
antenna high impedance. The4 capacitor you have reffered to is the
capacitor on the resonant
loop circuit is the one that is used in all loops which provides for
changes in frequency. That capacitor is required so that changes in
the resonant resonant frequency of one resonant circuit can induce a
varing frequency on the
combination of two resonant circuits that I have now melded into one.
The antenna except for the use of the balun is exactly as drawn
earlier.
Why is it that all do not apply one of the many available computor

programs
which consists of about ten lines on the 'wires' portion and let it go
at that
and then list advantages against disadvantages and we can then leave
it to the gurus that have the applical skills of comunication to
explain what is happening and why? This is not directed at you Richard
because I believe that you have already enunciated the salient points
of the antenna. What is now left is to list the advantages verses
disadvantages to see if I have a viable BEST
antenna. I would remind all that most innovations or approaches are a
product of using all available resources to meet an employers needs or
a pre ordained target. This is a way of life for all. One rarely
invents anything on a whim
natural laws in the main part are already known. Whorth while changes
usually
only come around by useing existing sources around which one can
innovate to provide a useable solution. I set a series of advantages
t5hat I wanted from an antenna and used existing resource to obtain
them. I have invented nothing
I have only used existing writings to achieve my requirements which
may well not meet the requirements of others. I am not an antenna
expert I am only a user
of what has been printed previously and subsequently forgotten because
it met my targetted means. Please do not try to make this antenna
complicated it is not,
It is as simple as my drawing. Frankly if Richard combined his
comments in this thread it is as a complete description of my antenna
that supplants all the
confusing descriptions that I have given. Well done.

Well, I done stepped in it now I guess...I did model the antenna you
are describing.
But with a slight difference...I used a 40 meter dipole instead of a
20m.
I saw a few interesting things about the loopadipole, but overall, I
think my first "off the cuff" remarks about that antenna are proving
to be fairly correc t. " I think anyway.." It is not really working as
you describe. To really describe all the testing I did would take a
few web pages to cover. I tested it on most all bands, 40-10 m.
Lets start with a 40m dipole in free space and note the gain on all
bands 40-10.
40m-2.13 dbi
30m-2.59 dbi
20m-3.67 dbi
17m-5.07 dbi
15m-2.91 dbi
12m-3.73 dbi
10m-3.89 dbi

If you used this antenna in the real world with a low loss feedline
such as ladder line, the antenna would be fairly efficient on all
bands.

Now lets compare the loop-dipole setup.
40m-1.78 dbi ---needed 164 pf to tune on 40m.
30m-1.13 dbi ---needed 76 pf to tune on 30m
20m-1.97 dbi ---needed 36.99 pf to tune on 20m, less on the higher
bands..
17m-2.40 dbi
15m-3.51 dbi with a very low Z input of about 2-3 ohms
10m-2.02 dbi

The only band that the loop-dipole showed a better gain was 15m, and I
think this is deceptive being as the impedance is so low.

As a comparison , the 20m magloop on it's own did -.031 dbi . So the
loopadipole on 20m is an improvement,"20m magloop and a 40m dipole"
but I think it's mostly parasitic gain. The loop seems to do most all

the radiating in that case. I can watch the current on these antennas, and can tell which radiator is doing most of the radiating. So anyway, wasn't a real scientific test, but seems to confirm my earlier guesses. If you have two sources, and one is low Z, and the other is high Z, most of the power will follow the low Z load if you are feeding with low Z coax. Also, I did properly tune the tuning cap on each band to get the best match I could. I found it very picky. I'm fairly sure in the real world, the antenna would be very sharp tuning in regard to the cap. As far as collinear gain, I can see ways you can change the pattern, but when you get to that point in tuning, the input Z is so low that I don't see how you could get much power to the antenna. So as far as collinear gain, using another dipole would be a much better plan. Anyway, you asked someone to model it, and I did it. "I said I would.." It seems to not work as you describe. BTW, I couldn't use Roy's program for this as the demo doesn't have enough segments, and I've been too cheap to order a full working program of EZNEC. I should do that one of these days, as EZNEC has a few advantages I think. So anyway, I ended up using MMANA. One reason was it already had a 20m magloop already made up and ready to go. That made it much easier as I didn't have to design a magloop model from scratch. All I had to do was add a dipole to the loop. I used seperate sources in phase to feed the loop, and the dipole. As far as testing the loop-dipole, the current distribution plots tell a lot. You can tell which element is doing the bulk of radiating. When the dipole shows a hi-z, as it does on 20m, "using a 40m dipole", the loop is doing most of the radiating. And it's not real efficient either. "As I earlier guessed". Of course, if anyone has any problems with my testing methods, I'm all ears...Or should I say, eyes, here on my puter monitor. MK

2248. FRACTAL ANTENNA DEBATE QUALIFICATION CHALLENGE

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-03 17:40:14 UTC
From: Richard Clark <kb7qhc@attbi.com>
Message-ID: <lq1okus2bgvefa1u39mb7a5irfuqlarugm@4ax.com>
Source record: 137490

Dear prospective debate participant,

To qualify to participate you must demonstrate skills in fractal antenna proficiency as demonstrated by your answers to the battery of questions that follow.

All questions apply to a 6th iteration Sierpinski, 5th resonance at 28.41MHz, built from #14 wire, over 48 radials, 0.33wl radius, above Real/High Accuracy, Medium Ground:

1.) how tall is the radiator?

2.) how much wire is required to construct the radiator?

3.) in which direction is the greatest radiation?

4.) what is the bandwidth?

5.) what is its mismatch to 50 Ohms?

6.) what is its performance at 10ï¿½ elevation (any azimuth)?

7.) list the answers above that exceed a 28.41MHz resonant monopole in performance.

8.) list the lower four resonant frequencies.

9.) provide references to all answers above that cite peer reviewed, published literature; the citations must be focused on fractal issues and citations offered must lead to a specific, numeric answer for the battery question being responded to.

ONE correct answer (without citation) is sufficient to indicate a mastery of the topic.

73's

Marvin,
The antenna and feed line as you described will
be very little improvement over a feed line entirely
of coax. Rather than try to make one antenna work
all bands with the extenuating circumstances you have,
I think you would find that using multiple dipoles
fed from the same feed point, using coax feed line,
would probably be an improvement. There would be less
compromise (meaning losses), in the long run.

Hi Mark,

A lot of work indeed. As for a basis of comparison and to answer a
longstanding question of mine: is there more than a dB difference?
40m-down 0.3 dB - no
30m-down 1.4 dB - yes
20m-down 1.7 dB - yes
17m-down 2.6 dB - yes
15m-down 1.6 dB - yes
10m-down 1.8 dB - yes

When you consider that 280 dB is the ratio of total light output from the Sun to the light output from a two-cell flashlight, yes, that's a LOT. I remember being staggered when I came across an article on transatlantic cables where the total attenuation was, as I recall, in the tens of thousands of dB. Took me a while to believe it was true, but it is. As a ratio, it's impossible for me to comprehend. It's possible to get a signal from one end to the other in the face of this mind-boggling attenuation by putting amplifiers of sufficient gain and noise figure at frequent enough intervals along the cable.

The reason that path loss and cable loss calculations are different is that path loss isn't really loss. That is, the calculation assumes that nothing is really dissipated -- all it calculates is the thinning of the field as it expands with distance. Cable loss, on the other hand, is real loss, and it adds up quickly as Richard pointed out.

Unless you can rotate the antenna, gain doesn't mean much unless it just happens to be in the direction(s) you want. I could care less how much "gain" an antenna has if that gain is in any other direction that the one I'm using to communicate at the moment. What I regard as a good feature of a trapped dipole is that the pattern is essentially the same on all bands. I can point the antenna at the directions of interest, and it'll be effective to those regions on all bands. So what kind of pattern does Art's antenna have? Is it essentially the same on all bands like a trapped dipole, or does it split into multiple lobes on higher frequencies like the plain dipole?

If two antennas have the same gain, the relative gain is 1. For power, dB = 10 * log(ratio). 10 * log(1) = 10 * 0 = 0. So a relative gain (ratio) of 1 is 0 dB.

Marvin

As for myself, I use four (4) dipoles in parallel fed by coax through a 1 to 1 balun. They are cut for 10, 20, 40 and 80 meters and I had some trimming to do. This setup is up at about 25 feet in the center because I can't go any higher for now. With my Kenwood TS-570S, all HF amateur bands except 160 meters can be tuned with the auto tuner including 6 meters. If you need more information, use me email and remove ".nospam" at the end. Take care.

Ken wrote:

> Seven watts out of ten I can live with. Maybe that is what the

Antenna tuners are not perfect, and at high transformation ratios, you might expect efficiencies well below 90%, indeed 75% might be quite realistic from commercial ham products. (You generally can't look the efficiency up in a specification, antenna tuner manufacturers revel in the fact that it is difficult to produce a specification scheme that allows simple expression of the efficiency characteristics of a tuner that would allow apples with apples comparisions with competitive products.)

If you use a 600W PEP transmitter, and your tuner was 75% efficient, you will lose 150W PEP in the tuner, leaving 450W to the transmission line / antenna system. (I didn't say you were dissipating 150W in the tuner, the average power of an SSB transmitter under uncompressed speech modulation is probably about 13dB below PEP, so the dissipation might be around 7W.)

If your VSWR is 12 and you are using 100ft of RG-8/X at 3.6MHz, you are loosing 75% of the power in transmission line losses. Your 450W PEP is now 113W PEP at the antenna terminals.

Somehow, I am getting the message that this isn't what concerns you, but rather you are concerned with stray RF in the shack probably energy flowing into the shack on the outer of the feedline, and hence your determination to use a toroid somewhere.

RF in the shack might be a further symptom, but is not the primary problem.

I would be concerned with the overall efficiency of your tuner / feedline / antenna system and fix that first, then if necessary, address any issues with RF in the shack. You should be able to achieve tuner / feedline efficiency better than 60% without too much difficulty.

These are complex configurations, and there will be interaction between the sub-systems, but attacking the symptoms rather than the cause will not lead to quick and effective remediation.

Focus on the antenna and get its feedpoint impedance to a realistic value to feed with a long run of coax. The VSWR at your antenna terminals is huge (~50), and is not conducive to efficient operation of 100ft of RG-8/X.

If you can't get the VSWR on the coax below say, 3, you should think of better cable. For 100 ft at 3.6 MHz, RG-8/X with VSWR=5 has about the same loss (~0.9dB) as 9913 with VSWR=8.

Most commercial SWR meters assume Z0=50 ohms and report accordingly.
Since the RS SWR meter is in a 50 ohm environment, there's no reason
to suspect the readings are grossly inaccurate. Vectorally adding a
calibrated sensed voltage in phase with the main voltage to a calibrated
sensed voltage in phase with the main current yields a voltage proportional
to forward power, i.e. the reflected energy is phased out of the measurement
assuming the calibration boundary conditions are met. Anyone who has
waded through the vector math associated with a wattmeter has been rewarded
with an understanding of the required boundary conditions and the accuracy
of the instrument. This applies to cheap RS SWR/power meters as well as
Bird wattmeters.

>

I think this is unfair.

Cushcraft is obviously aware of the issues and solves them. From time to time we all see these gripes on this NG, and as best as I can tell, all of them get resolved. So why is it a 'downhill spiral'?

The fact is that its hard to be in business selling ham radio antennas, or anything else to hams for that matter. I suspect the margins on ham antennas are VERY low and has gone down--not up-- in the last twenty years. Most OEM's would answer that challenge by going offshore. Obviously Cushcraft is an American company which , I presume, takes pride in being an American OEM.

I just looked at their news page and they make a comment on defining a new focus on wireless devices, if I read that correctly. One would hope, for the sake of needy hams, that they don't chuck the ham antenna business. I see no indication of that, mind you, but its a tough road out there selling to a smaller--and aging-- ham audience.

If one of the remaining ham antenna companies moves on to other markets, many, many hams will be scrambling for alternatives.

Not good for the ham community.

Just my opinions, take them or leave them as you wish.

But remember, that's into the transmission line. Someone else calculated a transmission line loss of 6dB so you are getting only 1.75 watts to the antenna if that figure is correct. In other words, the efficiency on that band appears to be about 25% neglecting tuner losses. Is 25% efficiency good or bad? Well, that's pretty good for a 40m mobile antenna. Only you can decide if that's good enough for your present application.

> What about my other question? WIll putting a ferrite toroid (with say
> 10 turns of the coax feedline) around 40 ft away from the feed point

It will probably help but you will probably not be able to tell the difference except maybe for a reduction of "RF in the shack". The basic problem is the high SWR on the coax and it seems to have been designed that way. Take a look at my web page for an efficient solution to an all-HF-band dipole.

What this does is to align the lobes at the frequency where the element is about 3/2 wavelengths long, changing the pattern from the 4 lobed pattern of a straight 3/2 wavelength dipole to a two lobed (bidirectional) pattern. This is the shortest practical "V beam", which you'll find described in various handbooks. If you take, say, a 40 meter dipole and bend the legs 30 degrees each, you'll have a very nice bidirectional antenna for 15 meters, and it won't have much of an effect on the pattern at 40 meters. I've done this, and had quite an effective antenna for Europe on 15 as a result, along with a decent 40 meter antenna. It's done with TV antennas because one group of VHF channels is in a frequency range that's about 3 times the frequency of another group of channels. So by bending the elements the beam is effective for both groups.

I wouldn't expect the technique to do much for you except on bands that are related by an odd frequency ratio (3, 5, etc.). And then, it would be tricky to come up with element spacings that would give satisfactory performance on both bands. The criteria for a decent TV antenna are somewhat different than for an amateur transmitting beam. It might be possible, though, to come up with a workable design.

You might use the technique to get additional gain on a single band, by optimizing the beam with 3/2 wavelength elements. But it might be more beneficial to simply use 1/2 wave elements and more of them instead. There were some articles some years ago (in Ham Radio if I recall correctly) describing Yagis with strangely shaped elements of unusual length in order to optimize performance. It never caught on, though, probably because of the difficulty in constructing them.

Roy Lewallen, W7EL

Hi David,

This is the simplest way to shape elements, and affords about a 1-1.5 dB addition of gain. It is impractical on HF trapped beams because of the shear it adds to the clamps. You can DO it, but its more expensive mechanically and less robust.

TV antennas are, of course, smaller, and have much shorter, lighter, and thinner tubed elements.

73,
Chip N1IR

I have made 150 DXCC contacts (confirmed) on 10M with this antenna w/
radials. The time period was 18 months.
I use it for 10 - 12 meters only. I use a G5RV for 15 - 80 meters.

I would assume the 250 ft wire would do much better than your 80m dipole.
Get some wire at Home Depot and give it a try.

Looks like a bent monopole and it's performance is likely fairly dependent on the integrity of the ground system underneath it. I wouldn't buy into the H/V component stuff too much--the highest current levels will occur in the vertical portion of the radiator. Nothing magic at all in this configuration--it's a top-loaded monopole.

I was given a 4 element cubical quad last night by a good old ham buddies of mine. It was a commercial antenna. The condition is excellent but I was wondering if anyone had the manual associated with its manufacture. The only identifying mark is on the boom to mast clamp. "Kirk" ....The only thing I have found associated with the name "Kirk" and quads is an article back in ARRL archives about an antenna by Sky Lane Products with a reference to "Kirk" The fiberglass arms are 9 feet in length and the hubs are beautifully manufactured out of aluminum (cast) The boom is 2" OD.

So anyone remember this antenna? The article was a review in Nov of 75 Qst. If anyone has that and could see if it is on a 4 element 2 band quad. I believe 10/15 meters. Feed with quarterwave matching sections of RG-11. I have not measured them yet, but I am sure it was for 10 and 15....any help would be appreciated greatly.

TIA

K7FU

Roy Lewallen <w7el@eznec.com> wrote in message So what kind of
> pattern does Art's antenna have? Is it essentially the same on all bands
> like a trapped dipole, or does it split into multiple lobes on higher
> frequencies like the plain dipole?

The pattern of the one I tried was fairly omnidirectional on most bands. Mostly like a distorted magloop, except on 40 and 15m. 15 meters had some pretty strange lobes, but I think that is due to the 40m dipole being resonant as a 3/4 wave on 15m and having a greater effect than say 17 or 12 or 10 meters. The main point of my test was not really to compare gains, but to show that when you have two elements, one a low Z, and one a hi Z, and you are feeding with low Z coax, that the hi-z element will not accept too much power, and basically be ignored. "Same as if running parallel 40/20 dipoles with a single 52 ohm coax". That scenario would occur if you were using Art's antenna on 20m. "40m dipole with a square magloop 1 meter long per side tuned with a 36 pf cap. As far as I can tell, the loop is accepting the bulk of the power. The magloop is in the center of the dipole, right next to it. As far as I can tell, this is the description Art gave for the antenna. Now, if you could feed the magloop and the dipole with each having it's own autotuner at each antenna, it would be a different story I would think. They should equally split the power from the rig. But I don't see any reason or real advantage to doing that over the single dipole with the autotuner. If I wanted to run two antennas and change the phasing to steer, I'd rather use a second dipole, not a small loop as a second antenna. To my way of thinking, adding a small fairly inefficient antenna in parallel with a fairly efficient antenna will always result in a loss of overall efficiency. Say as in connecting a dummy load in parallel with a tuned dipole at the feedpoint. I would think your signal would drop by appx 3 db if both were equal 50 ohm loads. Am I making an error here? :/ I don't want to lead any astray with any self induced bafflegab I might come up with... MK

Charlie Gallo wrote:
"Don`t you mean 1 dB gain? It is a ratio."

Indeed the power ratio has a value of one. That`s why the dB value is zero. Plus 1 dB is a gain. Minus 1 dB is a loss. Zero dB is the same power in and out, that is, zero gain and zero loss.

Roy Lewallen, W7EL already hit the nail on the head. The ratio of two equals is one. But dB`s are logarithmic, using a base of 10.

I am only replying to share a memory aid which works for me. I just remember to start with the value of an exponent.

The logarithm of a number is the power or exponent that the base, a fixed number, (in decibels it`s 10), must be raised to so that the result is a desired number called the antilogarithm.

Why the complication? So we can add and subtract instead of multiplying and dividing. Also, so we can multiply and divide by exponents instead of raising to powers and exttracting roots. It really is simpler.

In our example, the power ratio is one. The first question is: What power does the base 10 have to be raised to, to equal an antilogarithm of 1.00, the value of our power ratio. Our case is especially easy because it so happens that any number raised to the zero power has a value of one (1.00).

No need to worry in this special case about 10x or 20x for power or voltage ratios. Either value multiplied by zero equals zero.

Best regards, Richard Harrison, KB5WZI

sting methods, I'm all ears...Or should I say, eyes, here on my
> puter monitor. MK

I don't think your aproach is quite fair, you have made changes.
As Roy stated, an antenna with directivity is some what lacking if it
cannot be rotated and I fully agree, rotateability is a very
important requirement in my search on this antenna. Just do as I said
earlier using a 20 meter dipole
as one resonator, add a parallel circuit to it which includes a
variable capacitor (minimum 10-40 Pico as with the normal loop
antenna.) This parallel circuit will be around 40-50 inches either
side of the center with say 6-12 inches distance spacing but connected
to the main 20 meter dipole. For starters use a horizontal dipole
length of around 200 inches aside.

I really did not want to have elements longer than this because of ROTATION requirements and so this became my maximum 'airspace' for this antenna.
Method of feeding the antenna can be of your choice and again for starters you can use the connecting two junctions of the parallel circuit for your choice of best feed methods.
All impedances at the feed point which I assumed would be a gamma match
MUST be 50 ohms or above which was another one of my requirements. You can choose 200 ohms so any analysis will not introduce a 'apples and oranges' argument. At no time in the range of 20 thru 10 Mhz must the pattern deviate from a the normal dipole figure 8 pattern or provide LESS gain,
again a major requirement of mine.
So if you are getting impedances below that figure (50 ohms) it would not meet my requirements as it tends to affect efficiency, my last requirement.

PLEASE, do not introduce differences to my original drawing as that solicits
free rein to many who wish for failure. Again, use the dimension for starters
and it will put you in the ballpark from which you can make minor corrections
to maximise gains , efficiency and a common impedance value at the comb antenna feed point. There is nothing missing in the above description and to standardise
I would suggest you stick to a 1 inch dia design of the members because it has to be rotatable and survive the inclement weather(ice included) we have in Central Illinois. If in doubt you are welcome to send private E mail except by doing that you omit infomation from others.For a final point the only moving part is the variable capacitor shown tho a balanced to unbalance balun can be used with a suitable ratio so that the impedace can be brought down to the standard 50 ohm coax. If the programs you have allowes for capacitor impedance
this is a real plus as you can plug in a figure 200 or above instead of playing with literal capacitance values.
Have a great week end

Art Unwin KB9MZ

Darn wind.....why couldn't it bend the driven element and directors
all the same so you could at least maintain the proper spacing between
elements 8-}

Poor attempt at wit aside; good luck getting things back in order.
Don't worry too much about getting the reflector dead-nuts back to
where it was - settle for as close as you can get without further
damaging the element.

Best of luck & 73,
Howard KE6MAK

Chirp said he doesn't want to hear any more about this. I said the
thread was closed. Nevertheless, Clinton won't go away (nothing new
here) and makes the following bewildering statement:

|Apparently, you were they guy they were thinking of went they started
|putting warning labels on gun barrels.

I happen to own guns, and I don't recall seeing one with a warning
label on the barrel. But standby let me check the closest one....

Nope. I just pulled my Ruger P95 out of my pocket, field stripped it
and the only thing it says on the barrel is "9mm X 19".

What this has to do with anything previous discussed is way beyond me.
I would ask you to clarify, but I doubt you can, so don't bother. You
obviously have the ability to read things that aren't there and your
post is proof positive.

When I was the responsible engineer for the Phoenix Missile
transmitter, I specified coaxial lines that *were* machined out of
solid silver, (I wanted to use gold but the program wouldn't go for
it.) Also, it isn't unusual when trying to reject a carrier in a lab
setup (say the input of a spectrum analyzer where insertion loss is a
non-issue) to purposely undercouple a cavity to increase the Q. So
each of my examples is "real-world", and since I can't read minds like
you can, could have been what Chirp was looking for.

But thanks for the reminder... I need to get out to the firing range
soon and keep in practice. There are a lot of nut cases out there.

Art Unwin, KB9MZ wrote:
"At no time in the range of 20 through 10 MHz must the pattern deviate from a normal dipole "figure 8" pattern---."

I think Art may have posted an implication that his loop resembled a delta match. If so, would it need to be large to produce broadside radiation to support the dipole radiation? Or if the loop is small with significant radiation, should it be perpendicular to the dipole for their nulls to coincide?

Best regards, Richard Harrison, KB5WZI

You might consider using a "shortened" dipole for 160 meters - that
is, a dipole with loading coils installed in the horizontal radiators.
In some cases these can actually be shorter than your 80 meter dipole,
if space is a problem.

Another possiblity is a 160/80 trap dipole.

But there's really no good substitute for getting the physical length
as close as possible to the required electrical length.

Richard, if it is the feed method that radiates gives a problem then
choose your own method of feed . My method of feed does radiate of
course, but it is of
no real consequence to me.

Source record: 137442

Hi,

In a site near mine a friend has is radio shack located very near
12/20 KV aerial power line. His antenna, a Levy, is placed 3 m high
and for one 2m from the line and the other about 6m aways from the
lines.

We observe a heavy QRM on the HF bands, at level S4-6 which does not
allow any QSO. The Levy placed over 6m away does not capture this QRM.

Is there a solution to remove this QRM, excepting to move the aerial
away from the power line ?
I think about chocke and other solenoids ? Do you know such anti RFI
devices ? Some brands/models ? Are there efficient ? Is a big gun like
IC-775DSP able to reject such heavy QRM thanks to is excellent N.B.
able to suppress pulsed noises?

Thanks
Thierry, ONL5183

Well, I used the RG-8/X because I was told it was more than adequate
for a 100 ft. run on HF. I do not understand why folks think it is OK
if it so lossy on 80M.

I have two options. I left slack in the RG-8/X because I might yet
relocate my shack. I could trim it to around 75 ft. Any reason to
think this will greatly improve the situation?

Because most of the feedline run from my current shack location is in
my attic, I could switch to 75 ft. of ladder line all the way from my
tuner (MFJ-986) -- which accommodates ladder line and has a built-in
4:1 balun -- to the antenna's terminals. Will this solve my problem?
Are there any drawbacks?

I used the MFJ-1026 Noise Canceller to reduce power line BUZZ from S-9 down
to S-3. The key is to couple only the interference and not the desired
signal into the Aux input. Once my neighbor's pole mounted power
transformer's arcing finally caught fire the problem was gone.

I think your antennas are too close to the power lines.

According to the Wirebook III, 100ft of RG8x on 80m has a loss of about
0.6dB/100ft on 80m when the SWR is 1:1. According to the ARRL Handbook
graph, a 12:1 SWR causes an additional loss of about 1.4dB for a total
of 2dB loss. I got into this discussion late so I may be missing something.

> I have two options. I left slack in the RG-8/X because I might yet

Slightly, not greatly.

That will solve the feedline loss problem and will move the matching
problems to a location where they are relatively easy to solve.

2305. Long wire Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-04 13:38:56 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <aijatt$4f3$1@slb1.atl.mindspring.net>
Source record: 137447

Hello:

Thanks to everyone for all the past help; really appreciate it.

I have rigged a simple 'long-wire" antenna around my attic walls, and then vertically down to my receiver on the floor below.
Works reasonably well. Do listening only, up to 30 MHz.

Many have suggested that a much better way of doing this would be to use coax from the receiver to where the
antenna actually starts the horizontal run/loop around the attic.

I understand that I would also need a Balun to match the coax Z to the 600 ohms Z or so of the long wire.

Just to learn a bit more-

Is the "only" advantage of this scheme, as contrasted to the long wire all the way, to minimize noise pickup?

The vertical run from my reciver on our upstairs floor to the attic does not go near any PC's, or AC lines.

Think it's still worth doing? Why?

If so, suggested coax type for (<30 MHz) (would be to 50 ohm Z receiver input) ?

Thanks,
Bob

Good luck! If the elements are tubular, then they will be kinked, and
it would be next to impossible to straighten them out. If they're sold,
and you try to bend them back, they'll probably break.

Time to call your home owners insurance...see if they can help.

That is the only advantage. But if you are not picking up household noise, there's no reason to add the coax. Even if you have the noise, and if you install the coax, since your antenna is in the attic, it may pick up household noise, anyway.

If nothing's broken, there's nothing to fix. And, if you don't plan to move your antenna away from the house, it may be a futile measure, to begin with.

Good luck...

From: Michael Taddeo <mike.taddeo@shaw.ca>
Message-ID: <3D4D4767.1B116B3F@shaw.ca>
Source record: 137453

Good morning all.

I have a vertical which was my first antenna. I pondered and looked at reviews and I ended up purchasing the Butternut HF9V. It's an all band 80 - 6m which I also bought the 160m kit as I am space challenged here in the city limits. If I would be doing this again I would not spend the money on the 160m but that's just my personal opinion. as for antenna performance, I cannot complain with the performance of the HF9V. I have it mounted 3' from the ground (feed point), and bought the radial kit which has improved the performance a lot. I have the installation of it on a web site so if your interested feel free to check it out. Will give somewhat a life sized view of the antenna.
I am a new amateur and in 3 weeks I worked over 30 countries off of the vertical. I now have a beam but I still use the vertical on 40 and 80 a lot. It was expensive I think for an antenna however it seems to work very well and I do not regret buying that antenna just the 160m kit. I would recommend the radial lit, its does make a huge difference.
You can view the installation here.
http://www.apothecarytech.ca/va6mjt
Good luck with the choice you make. There is also a beam available on my web site that I have posted as well for the spacially challenged lots and city limits. Feel free to e-mail me if you would like to know more, that was the purpose of the web site.
Thanks and have a great weekend !

I started this the other day before you started "this" thread. You did
not specify the band the dipole was measured to. You just said a
dipole and a loop.
I quote:
***As most of the 'old' wire designs use a transmission line to aid in
the phasing of an antenna so that gains from collinear designs can be
realised, it would appear to me that replacing traps,stubs, specific
transmission line lengths with a loop antenna addition would be more
user friendly, whether it is used for a fixed frequency or a multi
frequency antenna or even a trapped dipole antenna
Since many of the contributors to antenna articles are members ofthis
group
perhaps some could explain this ommision whether it is because of lack
of merit or because as a group we are more intent expressing
thedisadvantages***

>
>
> I don't think your aproach is quite fair, you have made changes.

No, I didn't. I just doubled the size of the antenna. Anyway, you
didn't specify any specific antenna until this thread. I asked you in
another post if the antenna I described was correct, and you didn't
say anything.

> As Roy stated, an antenna with directivity is some what lacking if it
> cannot be rotated and I fully agree, rotateability is a very
> important requirement in my search on this antenna. Just do as I said
> earlier using a 20 meter dipole

> side of the center with say 6-12 inches distance spacing but connected
> to the main 20 meter dipole. For starters use a horizontal dipole
> length of around 200 inches aside.

That sounds about like what I did, except for the longer dipole.

> I really did not want to have elements longer than this because of
> ROTATION requirements and so this became my maximum 'airspace' for
> this antenna.

It doesn't matter. This test was to see if that theory of operation
will work. Not to design a new antenna with exact sizes.

> Method of feeding the antenna can be of your choice and again for
> starters you can use the connecting two junctions of the parallel
> circuit for your choice of best feed methods.

I don't understand what you mean. I have two sources in parallel. One
to the dipole, which is not tuned, and one to the loop which is tuned
by the cap.
> All impedances at the feed point which I assumed would be a gamma
> match
> MUST be 50 ohms or above which was another one of my requirements.

How are you going to remotely tune a gamma match? The match would have
to be adjusted for each band. In the previous thread, you made no
mention of tuning the dipole. I have a hard time understanding your
description of the 20 m dipole version. I do not have a diagram of the
"resonance breaker".

> You can choose 200 ohms so any analysis will not introduce a 'apples
> and oranges' argument.

Choose 200 ohms for what? The impedance of the dipole?

At no time in the range of 20 thru 10 Mhz must
> the pattern deviate from a the normal dipole figure 8 pattern or
> provide LESS gain,
> again a major requirement of mine.

Good luck...The ONLY band that showed a fig 8 pattern was 40m. The
band the dipole was a 1/2 wave. Most all other bands had a pattern of
a distorted magloop. But of course, on those bands, the dipole showed

a high impedance in comparison to the loop which was tuned to match 50 ohms. Are you saying I must tune both the loop AND the dipole?
> So if you are getting impedances below that figure (50 ohms) it
> would not meet my requirements as it tends to affect efficiency, my
> last requirement.

I don't quite get what you mean here either. In most of the cases I tried the feed impedance was lower than 50 ohms.
>

> description and to standardise

Are you serious? What drawing? From your description of "this threads" antenna, I still don't really have any idea what you mean as far as feeding.

> I would suggest you stick to a 1 inch dia design of the members
> because it has to be rotatable and survive the inclement weather(ice

How is that going to effect the electrical properties?

For a final point the only moving part is the variable
> capacitor shown tho a balanced to unbalance balun can be used with a
> suitable ratio so that the impedace can be brought down to the
> standard 50 ohm coax. If the programs you have allowes for capacitor
> impedance
> this is a real plus as you can plug in a figure 200 or above instead
> of playing with literal capacitance values.

You have me nearly totally confused I'm afraid. If the only movable part allowed is the cap, how are you going to have an adjustable gamma match to feed the dipole? As far as the cap, why would I not want to use literal values?
I'm afraid with this design, either you are going to have to model it, or you are going to have to draw a picture or something. You have me nearly totally lost. The "gamma match" for one thing. A gamma match will have to be retuned for each band in use. I'm assuming you are matching the dipole with the gamma match??? MK

This drawing is almost exactly what I made, except double the size of the dipole. The loop I used was 1 meter "appx 3 ft" per side. Now , where does the gamma match come in? Hummm, it just occured to me. Are you using the dipole wire as the "4th" side of the loop? In that case, you would seem to have an ajustable gamma match of sorts. ??? In the model I made the loop was seperate with it's own 4 sides, and placed off to the side of the dipole. Now, if you are using this as a dipole fed with an adjustable gamma match, the pattern will be as for a 20m single dipole. IE: The patterns on the high bands will have pattern unlike a 1/2 wave dipole. It would be the same as using an autotuner at the dipole feedpoint. MK

2316. SWR/wattmeters

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-04 18:20:44 UTC
From: CAM <w5dxp@hotmail.com>
Message-ID: <3D4D707C.836E84F8@hotmail.com>
Source record: 137459

There seems to be some confusion about wattmeters and forward/reflected power. Before displaying forward "power", the wattmeter uses a directional coupler to separate the forward values from the reflected values. This is done by vectorally adding two phasor voltages proportional to the total voltage and total current after calibrating the wattmeter for a particular characteristic impedance. This effectively changes the standing wave to forward and reflected traveling waves.

Let's say that a particular wattmeter has a voltage divider to give us a voltage proportional to the total voltage and a toroidal pickup coil to give us a voltage proportional to the total current. Using a 200 watt source, we calibrate the instrument for Z0=50 ohms into a 50 ohm load.

Total voltage equals 100 volts. Voltage divider voltage equals 10 volts. Total current equals 2 amps. Toroidal pickup voltage equals 10 volts. Since these two voltages are in phase, vectorally adding them yields 20 volts. So 20 volts indicates 200 watts. At any 50 ohm point up and down the 50 ohm coax, these same conditions will exist (neglecting losses).

Let's say we move a quarter-wavelength up or down the coax from a 50 ohm point and the SWR is 5.83:1 which means that the reflected power is one half of the forward power. The following conditions exist. Total voltage equals 170.7 volts. Voltage divider voltage equals 17.07 volts. Total current equals 0.586 amps. Toroidal pickup voltage equals 2.93 volts. Since these two voltages are in phase, vectorally adding them yields 20 volts. 20 volts indicates 200 watts, just as before. Note that we are measuring at the voltage maximum point instead of the above current maximum point.

Let's say we move 1/8 wavelength up or down the coax from either of the above two points. The forward voltage is 90 degrees out of phase with the reflected voltage. Their sum is 122.47 volts. The forward current is 90 degrees out of phase with the reflected current. Their sum is 2.449 amps. The phase angle between the total voltage and total current is 70.52 degrees. The voltage divider voltage will be 12.247 volts at (assume) zero degrees. The toroidal pickup voltage will be 12.247 volts at 70.52 degrees. Vectorally adding 12.247 volts at zero degrees with 12.247 volts at 70.52 yields 20 volts again indicating forward power equals 200 watts.

In a lossless transmission line where the SWR/wattmeter is calibrated for the characteristic impedance of the line, the wattmeter will read the same forward power no matter where the wattmeter is located up and down the line and no matter what the SWR (within reason). A Bird wattmeter is guaranteed to read within 5% of the actual value.

In used the word 'impedance' where the term should be REACTANCE. For
those who are now getting in to an unfamiliar area, the capacitance
used in a loop antenna
must have consistant impedance and is chosen by use of the graph
supplied in the Handbook which pretty much relies on the MINIMUM
variable capacitor
value that you can obtain bearing in mind that when using the lowest
capacitance that supplies the constant reactance and also meets the
design range
requirement rarely agrees with in the field trials because of stray
capacitance.
So again the term should have been REACTANCE in ohms which when used
in sweep programs (I believe that W7EL programs can handle) gets rid
of the varying capacitance struggle for those not adept as some with
antenna computor prorams
in which I include myself. For those unfamiliar with the chart I
quoted a figure of around 220 ohms makes a nice fit for the frequency
range when using
butter fly type varying capacitors that are in most junk boxes.

Regards
Art Unwin KB9MZ

My son Roger who is a "name" in computing informs me that my laptop
has a virus
which I believe explains a lot to me when letters appear or do not
appear
on my copy of the post yet mysteriously appear/disappear on google
posts.
Help is at hand, I am getting a 'hand me down' laptop which is also

faster which will be in use this week ! Thanks son, if only you was close enough to also transfer info from this laptop to your old one. The virus reminds me of one that my co workers played on me when I was tring to debug a fortran program of mine .I was very unhappy tho they whooped into laughter as some of the numbers slid to the bottom of the screen and disappeared
unnoticed by me.

Ok, I remade the antenna to match this picture. 20m dipole, and a loop with those dimensions. The "4th side" of the loop nearest the dipole, is made from the dipole itself. An adustable matching device.
Actually, almost seems to be an adjustable hairpin match it would seem. The antenna worked no problem on all bands 20-10. I adjusted the cap for each band to get a match under 2:1. As I earlier expected, the antenna acts the same as a dipole fed with an autotuner.
It has the same pattern, and gains as any other 20m dipole fed on all bands with an autotuner or low loss ladder line. Just to make sure, does this picture equal what you describe?

http://web.wt.net/~nm5k/loopole.jpg

That is the basic picture taken in the modeling program. To match on 20m took 5 pf. 17m, 44 pf. 15m, 30 pf, 12m, 18 pf, 10m, 12 pf. As you can see I prefer literal cap values...:) The antenna works, but no different than any other 20m dipole. You are just using a different version of an autotuner. The antenna would act the same with one of those fancy SGC autotuners. Or as far as I can tell anyway. BTW, it's really not that much work for me to do this. I'm fairly fast...The first test probably didn't take me over an hour total time. This one, less. MK

2319. Thrust bearing

Newsgroup: rec.radio.amateur.antenna

So far I have found 3 sources of thrust bearings:

1. Glen Martin TB-25 approx $90
2. RadioShack 940-0014 $80
3. Yeasu GS-065 (not sure of manufacture) $50

I need a thrust bearing for a 2 inch mast. Any one have any other sources ?

Any help is greatly appreciated.

Hi Jeff,

Aren't Facts kewel?

One fact that stares us straight in the face is that the biggest and
best of the eh/cfa/fractal belief circle cannot answer a single,
common question about a fractal antenna!

As you were guessing, you do not qualify; however, I will allow you to
go to the standby list. The classification of standby means that you
may only occupy the debate floor if and only if only one other
prospective participant passes the qualification trial.

If two, or more, manage to pass -
well heck, we know that ain't gonna happen! You alone have shown
mastery into the intracies of the fractal: it's not much more than
guessing.

Jeff, you is da winna! (sorry about the rï¿½sumï¿½ stain)

Source record: 137466

Hi,

Am using a random wire presently, for listening only, below 30 MHz.
Runs around my attic, and then down to my receiver.

It works, but not what I would hope for.

Would anyone care to suggest an antenna I could purchase, and still mount in the attic, of
"reasonable size," for 100 KHz to 30 MHz ?

Would want an Omni directional one, and hopefully for not more than $100, or so.

Thanks,
Bob

No need to be sorry Reg, it is taken as a sign of weakness over here.
I remember sending you an E mail when you first appeared on this group
to let you know what can happen to new boys. Again I was wrong, I wish
I can handle things as well as you have done.
I looked at your page a few years back when I was getting pummelled
on this net prior to it becoming Google. As always unless I spend a
lot of time
studying things I get all washed up. I believe it was the 'all zipped
up'
comment that got to me and I could not down load and at the same time
I left the the newsgroup.
As you can see I am back banging away rather hopelessly on that same
old antenna again in the futile hope that a 'guru' or 'name' will come
along and give it a go so that I can lift my head up high again. But
it is not looking good
so far because as it looks so simple it cannot possibly work.
To say that it works at my place and I knew one other ham built it an
in array form is not good enough since hams have become so leary of
the new and
proclaimed gain figures e.t.c.
I'll never let the subject go Reg and will fight to the end since I
know it works as I say but, apparently my engineering basics
explanations do not cut the mustard.
Cheers and beers, take care of your self
Art

2329. Re: Antenna Suggestions For <30 MHz, Listening Only - For Attic ?

Newsgroup: rec.radio.amateur.antenna

Source record: 137371

Bob,
Actually, you're probably using about as
'good' an antenna as any, for a 'wide band'
antenna and for receiving only, and given that
it has to be in your attic. Of course, if you
could get it higher (and outside) it would 'do'
better. If you're interested in particular
bands, you can cut the antenna for those bands,
which should help a bit. Very few commercially
made antennas are really worth putting in an
attic, unless you have a very good sized attic.
Good luck...
'Doc

Are you reading the graph correctly? The graph in my copy of the
handbook indicates that the VSWR is measured at the load.

The VSWR indicated at the tuner end of the coax is 12, my reckoning is
that with 0.55dB loss, the VSWR at the antenna end of the coax is 50.

I calculated additional line loss due to VSWR at 5.6dB.

For a ham, I'd say the single best resource would be a copy of the
ARRL antenna handbook. And that cover many construction points also.
The small orange Bill Orr antenna handbook is a good one if you want
to see a lot of different antenna projects in one small book. Many
easy to build. The large ARRL book covers more theory though. MK

2333. Delta Loop for 160m

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-04 21:02:57 UTC
From: G4VGO <rmread@attglobal.net>
Message-ID: <3d4d997c_3@news2.prserv.net>
Source record: 137375

I read ON4UN's book concerning full wave 160 metre loops. Has anyone had experience actually using one? I am about to begin a project that will hopefully end up with a 160m full sized delta loop up about 20 metres at the base, with the apex around 180 metres.

For vertical take-off where would the best feed point be?

Thanks

Bob G4VGO

You can also bend the the legs of the antenna to make a "Z" shape with
little adverse effects. Certainly better than using inductive loading.
I compared them. In his case, it depends to a large degree what
distance he wants to work. Close in within about 400-500 miles, a
dipole, even loaded, will outdo the T vertical on the high angle
stuff. "Usually"! But it's quite possible the 22 ft tall 80m T
vertical could win to longer haul stuff if the ground conditions were
good enough to avoid excess loss. It should also have a greater
groundwave signal than the dipole if local stuff is what he would want
to work. MK

Bill, N3WK wrote:
"The transmit antenna contributes gain and the receive antenna
contributes gain."

Bill is on target. When using those logarithmic decibels to do a
microwave path analysis, we add all the dB gains (both antennas) and
subtract all the dB losses to the +dBm from the transmitter to arrive at
the -dBm received carrier power to the receiver.

Best regards, Richard Harrison, KB5WZI

It IS more than adequate for 100ft on 3.6MHz if the VSWR is less than 3. Total line loss (matched line loss + additional loss due to operation at VSWR>1 is less than 1dB - not good, but adequate).

Sounds like searching for yet another work around.

You reported measured VSWR of 12 at the tuner end of 100ft of RG-8/X on 3.6MHz. If the measurement is correct, and the cable is not faulty (ie, it conforms to spec), and your measurement of the cable length is correct, we can calculate that the VSWR at the antenna end of the coax is 50.

Is the antenna supposed to have VSWR of 50 (measured at the antenna terminals)? If not, fix the antenna. (I cannot believe that anyone would sell an antenna for HF intended for coax connection operating with VSWR=50.)

2338. GPS antenna design questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-04 21:21:56 UTC
From: "Alexander S. Wood" <alec_wood@dont.spam.me.ntlworld.com>
Message-ID: <UWg39.2635$tm4.22365@newsfep3-gui.server.ntli.net>
Source record: 137380

What are the general requirements? I've tried crossed dipoles without much success. The only commercial antennas available here in the UK (that I have seen) cost in the region of £50 (about $75), I am sure I must be able to do one cheaper, and hopefully learn something while doing it.

Has anyone got any good reccommendations for what will be a vehicle mounted antenna. It could be active or passive. The coax run to the receiver will be about 4m if externally mounted. I can't mount it behind the windscreen since mine is heated and thus full of wires.

The application is APRS using a Motorola GPS Rx board and a custom PIC based decoder/TNC controller.

Thanks in advance

Alec Wood M1BNK
Teesside UK

Dennis Ferguson wrote:
"Now suppose I instead consider two parallel 1/4-Lambda monopoles on a perfect ground plane----."

Gain is identical for a dipole and for a monopole with its image. The radiated field intensity, volts per meter, is directly proportional to current in the antenna. The impedance of the monopole is half that of the dipole. When you radiate the same power, there is more current in the monopole.

Best regards, Richard Harrison, KB5WZI

Once again, the manure wagon is under way...

Nobody gives a crap about your inflated claims. The fractal antenna has NOTHING special going for it. Given the same amount of wire, there are any number of configurations that will produce equal or greater results in the same given physical area.

You want him to debate you, Steve is smart enough to know that you simply want him to prove a negative while you wallow in bafflegab.

As I said, once again the manure wagon is under way...

O.K,the drawing is good, the capacitance values appear O.K. except the highest capacitance should be at the other end of the frequency range which I must assume you got it backwards when typing your post. The capacitance values will increase uniformly from one end of the range to the other with max value at the 14 M hz range as with any normal loop antenna.
(your values do not !)
Now I can only assume that you only plotted the current curve which cannot be improved upon when using dipoles of 1/2 wave length where current is at the zero
point at the ends of the structure (Max voltage)i.e 20 M

Now stay with me for the moment.
If you apply a 10 Mhz signal to a dipole cut for 20 you will still get max voltage points at the ends but each side will be out of phase with each other even tho voltage is a max at the physical ends. Thus for max gain with the given physical length we have we also have to change the phase on one side to match the other to get maximum collinear gain.
The other resonant circuit (the loop) does this for you
So unlike say the trapped dipole we use the whole original physical length given
rather than shortening the physical element to suit and with out the use of the feed line or stub.
So forget the feed matching so that a constant feed impedance can be obtained
thru out the range chosen and concentrate on checking whether you actually
have those capacitances backwards and run gain figures for other frequences
to plot gains with frequency, after which you can optimise all dimensions and
cap values to obtain constant impedances when used with a 4: 1 balun i.e 200 ohms.
On the subject of the loop and the dipole using the same member. The whole idea of getting maximume coupling is to make it one and the same. Less efficient
coupling by leaving a gap between the two circuits is fine but adds to complexity to the physical building of the antenna. All is then finished except to place the capacitor where there is less electrical stress is applied upon it.
Now it is exciting for me to see you follow this thru. E mail me at any time
as my server is taking forever to update the postings.

P.S.
Let us stick for the moment with the loop/dipole combination name to reduce confusion in the group when other names are used.

Regards
Art

Beautiful spot.

Shame the desert didn't bloom this year.

I was out at Sedona,then up to Page and into Utah last month; closing the
Cococino Forest scared off the tourists.(I get to your area about 3-5 times a
year, depending on the year.)

Oh well, maybe my next biz trip will take me past Red Rock Canyon--when they
finally reopen it.

Nice car BTW.

The field strength from a monopole over an infinite ground plane will be sqrt(2) times the field strength from a dipole in free space, given the same input power. This is because the power from the monopole is concentrated in a half-space with half the volume of the dipole's environment. Consequently, the gain of a monopole over a ground plane is 3 dB greater than the gain of a dipole in free space, with both of course being compared to the same reference field strength. This isn't because of any fundamental difference in antennas, but rather the difference in environments -- a dipole over an infinite ground plane has considerably more gain than a dipole in free space. And a 1/4 wavelength ground plane antenna with horizontal radials has very nearly the same gain as a half wavelength vertical dipole.

Depending on how bad, sand paper or steel wool (if required) and then switch to CometT (or equivalent) cleanser. Rinse very well when you're done to ensure that no residue remains.

Larry,
Some fine steel-wool and elbow grease applied
at the joints of the tubing works fine. Also, you
might want to use some anti-oxidizing compound on
the joins when rebuilding the antenna. It doesn't
bother anything if the rest of the antenna isn't
nice and shiny, but clean the joints.

Larry,

Depends on what you want to do. I assume you only want to clean the parts that
make electrical contact, not the entire length of tubing. First, use a wire
brush to brush off the big stuff. Then, use a fine grit emery cloth NOT
sandpaper. One sheet of emery cloth goes farther than four sheets of
sandpaper. Wipe off all residue before assembling. When assembling, use one
of the commercially available "lubricants" that minimize aluminum oxidation.

You could also try using a product called Naval Jelly, but it isn't as common
as it used to be in stores.

73s,

Evan

2362. Re: Horizon antenna noise temperature ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-05 02:42:50 UTC

Message-ID: <ukrpgof6121t44@corp.supernews.com>
Source record: 137405

I did not notice this question at the time it was posted.
Years ago, W8PIL and I (then W8TBZ) wrote a paper on the ultimate limiting factor for vhf/uhf communications using antennas pointing at the horizon. It was published in QST about June 1961. I think that I still have printed copies of the paper. As I recall, the assumption was that a narrow beamwidth was to be used and that the noise limit was cosmic in origin. The paper is still the standard for what is possible. Today, the amount of man-made noise, which looks very random, from devices and transmitter spurs forms the noise limit. Over a period of several decades, a 150 MHz point-to-point circuit went from being NF limited to being almost unusable because of man-made noise. Both ends of the circuit were rural.

If one is far enough away from people, and one is using a high gain beam, the noise received depends on where the beam is pointed and the time.

I tried to be succinct.

Roy also wrote:
"The field strength from a monopole over an infinite ground plane will be sqrt (2) times the field strength from a dipole in free space, given the same input power."

That`s logical since the effective power is doubled.

Anytime radiation is restricted to half a sphere instead of a whole sphere, for a given amount of power, the power concentration is doubled in the hemisphere. That`s effectively double the power, or a gain of 3 db. This benefit is not confined to a single antenna type. This can accrue to various types of antennas, depending on their placements.

I did not propose placing one type of antenna in one environment and the other type of antenna being compared in a different environment.

Best regards, Richard Harrison, KB5WZI

Reg, G4FGQ wrote:
"A few days ago somebody asked how to calculate field strength from receiver input volts using a 1/4-wave vertical."

This isn`t the answer, but some might think this is related. Others would argue endlessly that it is not. B. Whitfield Griffith has related current into a 1/2-wave dipole with the field strength perpendicular to the dipole at a point one mile distant. I`ll try to give the gist of what he said.

One mile distance is often the standard used for field strength comparisons of antennas. It is several wavelengths distance in the AM broadcast band so that measurements are out of the induction fields of an antenna system.

The field produced by an antenna at a point in space can be calculated by integrating the current samples in an infinite number of infinitely small elements over the entire antenna and using this to determine the field. Almost the same determination can made by using antenna samples of practical size and simple arithmetic.

A half-wave dipole with one amp flowing at its center produces 37.42 mv/m at 1 mile, at a point perpendicular to the wire. Griffith used the simple arithmetic process for this result and presents it on page 327 of "Radio-Electronic Transmission Fundamentals". Field intensity is directly proportional to current in the antenna.

The field intensity produced by an antenna element, say 1-degree long can be doubled by the same current in an element 2 degrees in length.

We have the mv/m at one mile from a 1/2-wave dipole antenna in space. One mile is more than a wavelength so we don`t need to consider frequency. The induction fields are not a factor. The overall and incremental antenna lengths are expressed in terms of wavelength.

At two miles, the mv/m should measure about 19.

At 10 miles, the mv/m should measure about 3.7.

Down here on earth, loss will reduce measured field strength, and the incident and reflected signals may combine to produce more signal or less signal depending on the measuring point at one mile.

Best regards, Richard Harrison, KB5WZI

"The foregoing is beautifully simple and exact, easily understood by anyone who can do arithmetic."

A formula for radio signal attenuation due to expansion in free space has proved simple and effective. It may not be exact but gives answers agreeing closely enough with published graphs and tables.

I recently found it in print. It appears in Peter N. Saveskie`s "Radio Propagation Handbook" which is on ARRL`s bibliography list. I worked with Pete several years in Portugal. On page 326 Pete says:
"The loss between two isotropic antennae separated by one wavelength is 22.0 dB, thereafter increasing by 6.0 dB for each doubling of the inter-antenna distance."

|apparent oxidation on the aluminum tubing. Is there a recommended method of
|cleaning the aluminum?

I've mentioned this before here (I think). If you want to get it
really clean, inside and out (inside counts too you know) here's how I
did it.

I nailed together four 2 X 4's set on edge to make a form about a foot
wide and a bit longer than the longest piece of tubing. I lined this
with some heavy plastic sheet, like the black stuff used in
landscaping work, to make a liquid proof trough. Do this somewhere
out in the yard away from kids, dogs, and any plantings you want to
protect.

Fill this with water (hot if you have it) to about an inch from the
top and stir in a can of household lye. Old clothes, safety glasses
and gloves are recommended. Also keep a garden hose handy, you'll
need it for the next part anyway.

Drop in a few pieces of your tubing and let it fizz for a while.
Remove a piece and give it a quick rinse with the hose. Then take a
wet rag and wipe off the black smut that formed. If you have a nice
clean matt finish then you're done. If not, put it back for a few
more minutes and try again. Purists will do a dip in a weak acid
solution (vinegar) to neutralize the lye, but a good flushing with
clean water will do just fine.

In my case I used the material from a TH6DXX to build a 20 meter
3-element monobander. I cleaned everything, boom, element clamps,
elements, etc. I went through about 3 cans of lye over a two day
period but it beat the "elbow grease" method.

I was able to dispose of the liquid by dumping it on the ground. If
this isn't an option at your place then you have several gallons of
good drain cleaner.

I also strongly recommend that you use all stainless hardware and
no-ox on all of the interfaces. The larger ACE hardware stores have a
good selection of stainless stuff. I bought 1/4 bolts and
self-locking nuts by the boxfull at reasonable cost. Be sure to lube
the threads on all stainless fasteners to avoid galling.

73,

Wes

So far I have found 3 sources of thrust bearings:

1. Glen Martin TB-25 approx $90
2. RadioShack 940-0014 $80
3. Yeasu GS-065 (not sure of manufacture) $50

I need a thrust bearing for a 2 inch mast. Any one have any other sources ?

Any help is greatly appreciated.

Well, as it turns out, the antenna indeed resonates on 80M -- narrowly
at 3.899 MHz where SWR=1.5. At the bottom of the band -- where I want
to be -- SWR is 12. So, it looks like I will be lengthening the 80M
section of the antenna and going to ladder line.

I expected some compromises with a shortened dipole. However, it
would appear that the manufacturer's express assertion that this
antenna with a coax feedline will give good performance across all HF
bands if a wide-range tuner is used is not accurate. It does look,
however, that with some fiddling and ladder line, it can do the job.
Had I known that from the outset, I still would have bought this
antenna, but would have saved hours of testing and work.

"Somewhere in the book it tells you (For vertical take-off, where would the best feed point be?)."

See Fig 10-16 on page 10-10 of ON4UN`s excellent book. Vertical polarization gives lower radiation angle but gain is greater with horizontal polarization. You might install the loop with insulators for both polarization feedpoints and place a short across the unused feedpoint to try both.

Also look at Fig 10-14. Earth conductivity affects vertical polarization performance more than it affects horizontal polarization performance.

Fig 10-8 shows feedpoints for the desired polarizations.

I am switching from coax feedline to ladder line because my dipole is not resonant where I sometimes need to be and the attendant very high SWR is causing large losses in the coax. So I don't wind up running a feedline for the third time, I would appreciate a little guidance. I have read that which there is to read about it in the ARRL Antenna book, plus a little more.

1) Will the ladder line radiate at the non-resonant frequencies? Will twisting help?

2) The ladder line will run parallel and 1 ft away from a grounded horizontal galvanized A/C duct for 40 ft. Is this a problem? Will twisting help? Would 2 ft away make things much better?

3) I hope to install a simple DPDT switch in my shack so I can disconnect my radio from both leads and ground both leads. Any surprises lurking here? Any recommendations as to source?

5) I hope to go to 600 watts at some point. Is The Wireman's #552, 16 ga., ladder line the right choice? See: http://www.thewireman.com/balance.html

5) I need to be able to take apart the ladder line at a spot 12 ft. from the feedpoint in my attic. Can I use automobile-type, crimp-on, spade connectors? Or should I use a terminal block with screw posts? Or should I just solder it and forget about convenience? Is copper -on-steel easily solderable?

2378. General Rules for Debate

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-05 15:11:32 UTC
From: K4WGE <k4wge@msn.com>
Message-ID: <459a742fcc83756b5c39309f14a1a19e.8246@mygate.mailgate.org>
Source record: 137320

http://www.triviumpursuit.com/speech_debate/what_is_debate.htm

The following rules are taken from Competitive Debate Rules and Techniques by George McCoy Musgrave (1957)... :

"Debate, like many competitive activities, has rules and customs with which participants and judges should be thoroughly familiar. Until 1945, the rules were largely unwritten; they passed by word of mouth from debater to debater and from school to school. It is not surprising, then, to find some disagreement as to what they actually are.

In the last few years considerable progress has been made in the development of standards and procedures generally acceptable on a national basis. Widespread intersectional competition and national debate publications have accelerated this trend...

The Teams

The rules governing participants are these:
Rule 1. There are two teams. Each team consists of two or three speakers.
When the debate is arranged, agreement is reached as to whether two- or three-man teams will be employed. Two-man teams now predominate...

The Speeches

Rule 2a. The speeches and speaking time are divided equally between the two teams.
The tournament rules or debate contract specifies the amount of time allocated to each speech. The total speaking time generally runs about one hour including questioning periods.
Rule 2b. Each team has two or three constructive speeches.
It is customary for each member of the team to be allowed one constructive speech. Thus, if two-man teams are employed, there are two constructive speeches per team. If three-man teams are employed, there are three constructive speeches per team.
Rule 2c. Each team has from one to three rebuttal speeches.
In standard debate, it is customary for each participant to speak in rebuttal. ... The number of rebuttal speeches is, of course, specified in the pre-debate correspondence or tournament rules.
Rule 2d. The affirmative gives the first constructive speech, and the constructive speeches alternate: affirmative, negative, affirmative, negative.
Rule 2e. The negative gives the first rebuttal speech, and the rebuttals alternate; negative, affirmative, negative, affirmative.
Thus, the affirmative has both the first and last speeches of the

debate. This arrangement is designed to compensate for the affirmative's burden of proof, explained later.
Rule 2f. In Oregon type debate, each team has one or more questioning periods, in addition to the constructive speeches and rebuttals.
There are several versions of cross-examination debate. The arrangement to be used is agreed upon when the debate is being planned.

The Topic

When the topic is worded, whether by the national committed or by the local debaters, the following rule is applied:
Rule 3a. When worded as a proposition of policy, the topic requires the affirmative to support some specified action by some particular individual or group.
The proposition of policy takes the form, "Resolved, that the United States should grant statehood to Hawaii." Other wordings are possible and have been used in the past, but they have proved less satisfactory. The national high school and the national college topics have been phrased in this manner for so many years that other wordings are now generally considered improper except for international debate. The material in this book is based on the presumption that the topic is worded as a proposition of policy.
Of course, there are other requirements for a good topic. It should be interesting, clear, have one central idea, and not be one-sided. But even if these requirements are not met, it can still be debated; such requirements must be considered matters of good technique rather than rules.
Occasionally a contest hinges on the definition of a word or phrase in the topic. The rule is this:
Rule 3b. The affirmative has the right to make any reasonable definition of each of the terms of the proposition.
A "reasonable" definition generally means the definition intended when the proposition was phrased, or the technical definition of the term as used by professionals in that field. If the affirmative's definition is not reasonable, the negative should challenge it at the earliest opportunity.
Rule 3c. If the negative challenges the reasonableness of a definition by the affirmative, the judge must accept the definition of the team that shows better grounds for its interpretation of the term.
The judge is not expected to exercise his own taste in the matter, but to listen to the evidence and logic of the teams and to support the definition shown to be more reasonable.
Rule 3d. Once the negative has accepted the affirmative's definitions, it may not later object to them, even though it later develops that they are unreasonable. Failure of the negative to object to the affirmative's definitions in the first constructive speech following the definitions is equivalent to acceptance of them by the negative.
If the negative wishes to quarrel with the affirmative's interpretation of the topic, it must do so at once. Otherwise the debate might literally be half over before the teams have decided what they are arguing about. If the negative, through oversight, accepts or fails to

object to an unreasonable definition by the affirmative, it should not later be heard objecting that the definition was unreasonable.
"Trick" definitions are not encouraged. Unusual definitions are sometimes employed successfully by getting the negative to agree that they are reasonable before it realizes that they are not, but since strategic cases are always possible without resorting to such definitions, it is better to avoid them. They lead only to bickering and quibbling.
One practice, which has much to commend it, is for the two teams to agree on the definitions of any controversial terms in their pre-debate correspondence. These definitions are then included in the debate contract or tournament rules, and are announced by the chairman at the start of the contest.
Of course, all this does not mean that either team is required to define formally any term of the proposition. High school debaters do seem to prefer formal definitions, picking out the terms one by one ("By federal government, we mean..."). College debaters, on the other hand, often prefer to define the entire proposition by explaining the plan they are supporting. Either method is, of course, appropriate in either high school or college work.
The old argument about the meaning of the word "should" in the proposition still arises. Here is the generally accepted definition:
Rule 3e. The phrase "should adopt" or its equivalent means that the affirmative must show that the plan, if adopted, would be desirable. It does now in any way obligate the affirmative to show that the necessary approvals could be obtained.
For example, the constitutionality of the proposal is irrelevant; it must be presumed that the Constitution could be so amended if necessary. Similarly, the claim that too many voters or too many members of Congress are opposed to the bill for it to pass is irrelevant; the only question to be settled is whether or not the plan would be desirable if adopted.
On the other hand, the negative may choose to claim that the plan is not practicable that if it were put into effect it would not work, either immediately or at some future date. The plan certainly wouldn't be desirable if it didn't work, so this is a legitimate negative case which the affirmative must meet.
Rule 3f. The phrase "should adopt" or its equivalent obligates the affirmative to recommend that action be taken in the reasonably near future.
Ordinarily, no time limit is specified in the topic. Nevertheless, one is implied. The affirmative may allow a reasonable amount of time for working out the details and establishing the administrative functions, but delay until conditions have changed in some significant respect, or until (say) Great Britain tries the plan first, is not permissible.
If no such requirement as this existed, the affirmative might recommend that action be taken twenty years from now, when the plan could be adopted under highly favorable circumstances. The negative's position could be identical, and no debate would ensure. therefore, the affirmative must support reasonably prompt action.

Positions of the Teams

Sometimes the right of a team to recommend certain action is challenged. The limitations are not severe, but they should be clearly understood.
Rule 4a. The affirmative must advocate everything required by the topic itself.
If the affirmative fails to meet all of the requirements of the proposition, it fails in its burden of proof and consequently must lose the debate.
Rule 4b. The affirmative may work out the details of its plan as it sees fit. It may take on the burden of proving anything else it desires.
Of course, the more the affirmative advocates, the more it must prove, so the usual technique is to recommend as little as possible. However, if the affirmative does wish to recommend and support more than is required of it by the topic, the negative has no right to object. The affirmative is assuming the burden of proof for the entire enlarged plan, and if it fails to meet this responsibility, the negative wins.
Rule 4c. The negative may offer any counterplan that would be in order in a legislative assembly discussing the proposition.
The ideal counterplan is one that offers some change in principle from the affirmative proposal, and gives sufficient grounds for refecting the affirmative proposal. The counterplan actually offered, however, may be something less than ideal, and therefore it is important that each participant clearly understand what is permissible and what is not.
A counterplan which closely parallels the affirmative recommendation, differing only in minor respects, is adequate only if the negative shows that the difference between the two is so important that the affirmative plan should be rejected in favor of the negative proposal.
A counterplan based on surprise may, if successful, catch the affirmative unprepared. In the moment of anguish that comes when the affirmative realizes that it has no answer, there may be charges that the negative proposal is out of order. Actually, surprise in itself is perfectly legitimate. No proposal is ever out of order simply because it was not anticipated by the opposition.
Facetious and irrelevant counterplans are clearly out of order. Such plans would be useless in any event because they would not give logical grounds for rejecting the resolution.
Following legislative practice, disputed matter is admitted if there is doubt as to its admissibility.
Rule 4d. The affirmative must explain, upon demand by the negative, the major features and policies under which the proposed plan is to operate. If the negative recommends a counterplan, it has the same duty.
Neither team may leave its plan so vague as to prevent a reasonable attack by the opposition on grounds of practicability. For instance, when advocating a federal union of the nations of Europe, the affirmative, upon demand, must explain the basis for the selection of representatives from member countries that is, population, area, natural resources, literate population, or other method.
On the other hand, there is no obligation to explain minor details. The affirmative does not have to know how many representatives Luxembourg will have, so long as it explains the basis of Luxembourg's

representation. If the negative can show that the decision of the affirmative about an apparently minor detail of the plan is vitally important, then the affirmative must explain how that part of its plan will work; but if the negative attack is of the "hit-and-run" variety, the affirmative is under no obligation to answer each of these minor objections.

Sometimes an affirmative team decides to leave as much as possible to a commission or legislative body to decide so that the negative will have limited grounds on which to attack. This is permissible with regard to minor details, but if the negative demands an explanation of the major features of the plan, the affirmative is obligated to provide it.

Once a team has made known its position on major or minor issues, or even on small details, it is governed by the following rule:

Rule 4e. No revision of position of a team is permitted during the debate.

This rule is designed to prevent teams from wriggling out of contradictions between speakers by simply saying that they had revised their attitude in the meantime, Furthermore, it simplifies the proceedings and enables everyone concerned to follow the debate more easily; one can readily visualize the difficulty in pinning anyone down if speakers were permitted to shift their position whenever they chose.

When a team shifts ground on some issue, the judge should consider the point won by the opposing team. The only exception would be made when the revision is relatively minor and when, except for the shift of ground, the team making the point has a clearcut superiority on that particular issue.

Proof

A great deal has been written and said about the burden of proof, and certain misconceptions have arisen about the duty of the affirmative. The rule is simple:

Rule 5a. He who asserts must prove.

This principle applies equally to the two teams. Of course, the affirmative must show that its plan is desirable, which means that it must show that some benefits will result; otherwise it has failed to give reason for adopting the plan, and has lost the debate. The commonly heard statement that "the affirmative has the burden of proof" means that and nothing more.

On the other hand, if the negative wants the judge and audience to accept the idea that there are certain defects which outweigh the plan's good points, then it must assume the burden of proving that such disadvantages actually will result.

If the negative introduces a counterplan, it has the burden of showing how it is better than the affirmative's proposal; the affirmative then has the duty of establishing any alleged objections to the counterplan. In every instance, he who asserts must prove.

Rule 5b. In order to establish an assertion, the team must support it with enough evidence and logic to convince an intelligent but previously uninformed person that it is more reasonable to believe the assertion than to disbelieve it.

The amount of proof required in debating is generally less than that required in law. In law, the jury must be convinced beyond a reasonable doubt that the defendant is guilty in order to convict him; in debating, an assertion is established if it is supported by the weight of evidence and logic, even though there still may be room for doubt.

One further distinction is this: In law the jury may disbelieve evidence, even though its accuracy is not disputed. In debating, the judge is measuring the relative skill of the two teams, not deciding the "bedrock merits" of the matter in question. Therefore he is required to accept as valid all arguments backed with reasonable proof (as defined above) until overthrown by the opposing team.

A debate coach once remarked, "The implications here are pretty strong. Does this mean that the judge cannot penalize a team which uses a bare-faced lie as proof? Why not manufacture your evidence?" His point is well taken. Manufactured evidence is so rare in debate as to be almost non-existent, but conceivably it might happen some time. In that event, the following rule would cover the situation:

Rule 5c. Facts, presented in a debate as such, must be accurate.

If the judge is certain that the evidence is deliberately falsified, he is justified in giving the decision to the other team on this point alone. More often, it is simply a matter of interpretation of evidence, and if some error in logic is present, it is up to the other team to find it and point it out.

Rule 5d. Any restatement or quotation of an opponent's argument must be accurate.

A word-for-word quotation, in context, is ideal. This is ordinarily possible when the quotation is short or when one of the members of the team knows shorthand. Under most circumstances, however, the debater finds it necessary to paraphrase his opponent's remarks; for this purpose he needs careful notes and an understanding of his opponent's intent.

Misquotation, whether deliberate or not, unfairly places the other team in a false position and should be studiously avoided.

Rule 5e. Visual aids are permissible in debate. Once introduced, they become available for the opponents' use if desired.

On international questions, one team may desire to point out certain areas on a map. If this be done, the map may also be used by the opposing team. Consequently, it should be left in plain view of the audience, not rolled up and tucked under a table after the first speaker is through with it.

Rule 5f. One-sided visual aids must not be exhibited while an opponent is speaking, unless the opponent specifically requests that this be done.

Some teams prepare an outline of their case on a large poster, and exhibit this poster during the first constructive speech. If this be done, the poster should be removed at the end of the speech so that it does not distract from the attention given the next speaker.

If the next speaker feels that the constructive speech could be refuted more effectively with the poster in front of the audience, he may ask that it be put up again, in which case his request is, of course,

granted.
Preferably, visual aids should be introduced in the constructive speeches, rather than held until the rebuttals.

Refutation and Rebuttal
The rebuttal period is a time for refutation and summary; in fact, such emphasis has been placed on summary that some writers now refer to the "rebuttal-summary" period. Sometime one team believes that it has completely refuted the other team's arguments before the final speech starts, and then it may be devoted entirely to summary.
In all fairness to the opposing team, the constructive arguments of a team should be established in the constructive speeches, to allow time for the opposition to answer. Consequently, the following rule is well established:
Rule 8a. No new constructive arguments may be introduced in the rebuttal period.
A constructive argument is generally an alleged advantage or disadvantage in one of the proposed plans. All such arguments must be brought out in the constructive speeches.
Constructive arguments introduced in the rebuttal must be disregarded by the judge, with only one exception:
Rule 8b. New constructive arguments may be introduced in the rebuttal period if the rebuttal is the first opportunity to answer a direct question and if these new arguments answer the question.
The long-standing policy against new constructive arguments in the rebuttal period exists to protect teams from the last-minute introduction of new arguments by their opponents. If a team lets down the bars by an indiscreet question, it no longer deserves this protection; accordingly, the opposition may, if it desires, take advantage of the situation by introducing new constructive arguments in rebuttal. Such instances are rare because most teams find it desirable to introduce their constructive arguments early enough in the debate to support them with adequate evidence.
Rule 8c. Refutation may take place in any part of the debate and is not limited to the rebuttal period.
The above rule is so well understood that its mention would be unnecessary were it not that sometimes young debaters claim otherwise. "Refutation" includes the introduction of new evidence, when used to counter a point raised by the opposition.
Rule 8d. Either team, when advocating a plan of action, must explain that plan early enough in the debate so that the opposing team has a constructive speech in which to reply.
Advantages and disadvantages in a proposed plan of action are generally considered new constructive arguments; and new constructive arguments are not permitted in rebuttal (Rule 8a). Therefore, each team must give the other an opportunity to bring out new arguments of this kind before the rebuttals begin.
From the standpoint of the affirmative team, the rule is not particularly important. The affirmative can delay the explanation of its plan until the second constructive speech if it chooses, since the

negative still has a constructive speech in which to bring out the defects of the plan before the rebuttals.
From the standpoint of the negative team, however, the rule is significant. Where there are only two constructive speeches per team, the negative must propose any counterplan in its first constructive speech. If the negative waits until the second constructive speech to introduce the counterplan, the affirmative is forced to ignore it or present new constructive arguments in rebuttal.
If the affirmative is on its toes when the negative violates this principle, it can refuse to discuss the matter, pointing out that the negative left it no constructive time in which to bring out the disadvantages. The judge then considers the counterplan irrelevant, out of the debate, and does not consider it in his decision. This, in effect, penalizes the negative.
If, on the other hand, the affirmative chooses to meet the counterplan in the short time remaining, it does so knowing full well that it will be working under a handicap. Therefore, if the affirmative elects this course it is not entitled to any special sympathy; the judge simply reaches his decision on the basis of the arguments presented.
The last affirmative rebuttal presents special problems of its own, since it is the last speech of the debate and the negative has no opportunity for reply. One such problem is covered by this principle:
Rule 8e. The affirmative must, if possible, reply to the major negative arguments before the last rebuttal.
Suppose this rule were not followed. Suppose, for instance, that the affirmative had opportunity to answer some important negative argument earlier in the debate, but failed to do so until the last speech. The negative, having no speech in which to reply, is unfairly handicapped. If the negative rebuttalist anticipates this problem, he can make the affirmative look very bad by pointing out, as he summarizes, that the affirmative had opportunity to answer this argument earlier, and they did not do so, so any new defense dragged out at the last minute is under suspicion.
Suppose, however, that the negative does not anticipate the problem, and the affirmative does step out of bounds in that final speech. Suppose, for example, that the final speech contains a serious misquotation, or inaccurate facts that seem rather important, or new constructive arguments. What protection does the negative have? What can it do?
There are two methods for preventing unfairness of this kind. Either (1) the judge must be required to recognize and discard such material from the last rebuttal, or (2) some method must be developed to permit the negative to call the attention of the judge and audience to the situation. Since the negative team can recognize inaccurate quotations or facts more easily than the judge, the following rule seems to provide the preferable solution:
Rule 8f. If the negative believes that the affirmative is making unfair use of the last rebuttal, it may ask for the floor to point out the situation. The affirmative may then defend the statements in question or correct them and apologize.
If the judge determines that the negative charges are true, he penalizes

the affirmative by throwing out the arguments in question. If he determines that the negative charges are unjustified, no action is necessary. It seems preferable for the judge to state, before the affirmative speaker resumes his remarks, whether the arguments are to be thrown out or not, for only in this way will the affirmative rebuttalist know whether to continue in the same vein.
The judge makes no distinction between the last rebuttal and any other speech unless the negative points out some unfairness.
The time consumed in appeals and their settlement is not counted.

Judging

One basic principle underlies debate judging:
Rule 9a. The team doing the better debating is the winner.
Conceivably, more than one process might be employed to determine which team does the better debating. Indeed, since the beginning of intercollegiate debating a number of such methods have been proposed and utilized. Probably the most universally acceptable criterion would be this:
Rule 9b. The team doing what the proposition requires is the winner.
Debate topics are worded so that one team must succeed and one team must fail in meeting the requirements of the proposition. The successful team, having done the better debating, is declared victorious.
When the topic is expressed in the usual form as a proposition of policy, the judge's criterion for determining the winning team may be expressed in this form:
Rule 9c. The decision is given to the affirmative if it succeeds in showing that the proposed plan should be adopted. The decision is given to the negative if the affirmative fails to show that the proposal should be adopted.
The judge must remain strictly neutral and impartial with regard to the subject matter for debate. He cannot aid one team or the other by injecting his own personal opinions into the decision. This principle is applied in several ways:
Rule 9d. The judge must base his decision entirely on the material presented, without regard for other material which he may happen to possess.
Arguments or evidence which occur to the judge, but which are not employed in the debate, have no place in the decision. However, if the judge happens to possess some significant facts not employed in the debate, it would be helpful for him to mention them after his decision, as a suggestion for future use.
Rule 9e. The judge is required to accept as true all arguments backed by reasonable proof (as defined above) until such arguments are overthrown by the opposing team.
The judge has no right to consider an argument weak unless the opposing team shows that it is, or unless the team making the argument badly asserts it and fails to support it with adequate evidence or reasoning.
Rule 9f. The judge must not accept ideas which are not backed by reasonable proof.
Unsupported assertions and purely emotional appeals must not be

considered. The use of emotion is legitimate in driving home a point, and is to be encouraged in many instances, but the point must also be supported by evidence or logic if it is to be considered.
Impartiality also applies to the judgment of the debate techniques employed. Harlan puts it this way:
"The danger of using coaches for judges is that they have their own ideas about how best to prove each side, and, regardless of how good your proof might be, if you do not prove it as they would, there will be a tendency to discount your arguments."
Perhaps this does not apply to the majority of coaches who serve as judges. But in those instances where the coach-judge does swerve from impartiality, the criticism is valid. Each team has the right to make use of whatever arguments it desires, and the judge may not penalize a team for failing to make use of an argument or type of case he considers good. The entire decision must be based on what the teams accomplish, not on what the judge personally believes a good debate case on that subject to be.

Violations

Rules of debate exist to define the procedure and the playing field. They are similar to rules of football in that violation means a penalty of some sort but not necessarily loss of the game. Of course, in a tight situation the penalty could, in either game, mean the difference between victory and defeat.
Rules of debate are designed so that the teams suffer the natural consequences of their actions. There is no parallel in debate to football's five-yard penalty, but there is a close parallel to an out-of-bounds run in football: If the runner goes out of bounds, the play is stopped at that point; any gain made off the playing field is disallowed. In debate, any gain made outside of the established procedure is disallowed.
Suppose, for example, that a team brings up new constructive arguments in rebuttal. Since there is a rule against it, the judge would be required to disregard such arguments. This means that the offending team has wasted some of its time, which is the natural penalty one would expect. No additional penalty is placed on top of this natural one.
Again, suppose that a team makes assertions without proof. Since there is a rule which says that he who asserts must prove, the judge will decline to accept unsupported assertions. This is the natural penalty for violation of the rule. No additional penalty is inflicted.
This may be summarized as follows:
Rule 10. Any gains made outside of the established procedure are disallowed.

Wes, I have a few questions for you. Every time I have put together
old antennas, I just clean the pieces that join together, use anti-ox
and leave it at that. Now for the questions, why go to the trouble of
using caustic (remember Murphy's law?) materials to clean off the
whole antenna? Does this cleaning make it operate any better? Does
the oxidation of the surface of the aluminum, as long as it is not on
the joining surfaces cause some problem I am not aware of? Just
curious.
Thanks Dan
N9JBF

Back when I had Ladder Line coming into the shack and running through a big Nye Viking antenna tuner, I had intolerable EMI pickup from the computer and monitor in the shack here. Getting rid of the tuner and LL and replacing it with quality Coax made the interference go away. I probably still have a bit, but I don't notice it anymore.

If I were you, I would not let that LL come anywhere near the shack.

I have coax going outside to a choke balun where it couples to a carefully predetermined length of LL in the method suggested by wbdxp at

http://www.qsl.net/w5dxp/notuner.htm

You would think so, but I couldn't get it to tune using my normal
"guestimated" cap value. The 17m tuned with 44 pf. 15m needed 30 pf.
So you would think on 20m, you would need appx 55-65 pf, maybe more???
or so. But I could only get a good match on 20m using 5 pf. They are
not backwards. As you can see, from 17m on up, they seem normal.

> gain.
> The other resonant circuit (the loop) does this for you

But I don't really consider it another resonant circuit. Or element
anyway...I consider it an impedance matching device same as any other
gamma, delta, etc, match. To me, the whole system, loop matcher and
dipole, are one resonant circuit when tuned to match your 50 ohm coax.
As far as "collinear gain" , don't you need two elements?
I consider the dipole as one element. I consider the loop as a
matching device.
Sure, you can use L/C phasing to change direction, but I don't see how
you can do it with what you have. You are only feeding one element,
unless you split the elements?. If I'm missing something here, maybe
brighter bulbs will comment...

> So unlike say the trapped dipole we use the whole original physical
> length given
> rather than shortening the physical element to suit and with out the
> use of the feed line or stub.

But doesn't that rule out a "dipole like" pattern on all bands? I must
add though, that with only 20-10 meter use, the range is not large
enough to cause weird lobes on 10m. They just tighten up a bit.

> So forget the feed matching so that a constant feed impedance can be
> obtained
> thru out the range chosen

Huh???? You've lost me here...I don't see how I can do that even
without matching.

and concentrate on checking whether you
> actually
> have those capacitances backwards

Nope. They were not backwards. I modeled and saved each band tested as
a seperate antenna.

and run gain figures for other
> frequences
> to plot gains with frequency,

I've already done that. The gains were the same as any other 20m
dipole almost to a Tee from 20-10m.

after which you can optimise all
> dimensions and
> cap values to obtain constant impedances when used with a 4: 1 balun
> i.e 200 ohms.

You've lost me on this part. You don't need another balun. You have a
"gamma?" type matching device already. Unless maybe you want to
further reduce feedline currents...

> On the subject of the loop and the dipole using the same member. The

> coupling by leaving a gap between the two circuits is fine but adds to
> complexity to the physical building of the antenna. All is then
> finished except to place the capacitor where there is less electrical
> stress is applied upon it.

But in the antenna I'm modeling, there is no coupling from element to
element per say. I'm using an adjustable matching device. This 2nd
antenna is a whole different animal than the first I made. The first I
made that you didn't like, was two elements. A dipole and a loop. I
consider this one, one element. I think we have a difference of
opinion there. MK

I used MMANA which is from Japan. Same guy that makes MMSSTV. It was
the only freeware program I had that had the segment power to model
this accurately. "I'm cheap, and haven't bought any pay programs yet".
I don't have any of the above except for the eznec demo.
Well, let me take that back.. I might have NEC, but I haven't used it
much...
MMANA does generate a text file with the wires, sources,etc, etc, that
could be manually copied over to another program. I think it uses the
same basic engine as say elnec. Thats why I say eznec probably has an
advantage being it uses a better engine. "I think anyway, if I
remember right..". I'll zip up those text files for the antenna, and
each band, and post them on my server later..I'll post you a link
after I do. MK

Ken,
See if this helps;
1. Twisting the ladder line doesn't do much about the
feed line radiating. It does help keep the ladder line
from flopping in the wind (really).
2. With 450 ohm ladder line about 4 - 6" of clearance is
enough. A foot would be nice, and two feet would be even
nicer. Twisting the ladder line does little good.
3. A 'simple' DPDT switch isn't exactly the 'best' thing
to use. The contacts in the switch are not very far apart
so it wouldn't provide a 'lot' of isolation. If you can
find an old knife-switch (big one), or an old fuse box
with a knife switch, either would provide 'better' isolation.
4. Using 16 ga. ladder line should hold you to ~well~ over
legal limit.
5. Either will work. Another alternative is to use a 'Twist-
Lock', male and female 120 volt AC connectors. The 'Twist-
Lock' is to keep it from pulling loose. You have to be a bit
'creative' in how you get the ladder line into the connectors,
but it's no big deal, really.

Good luck, I think you'll like using the ladder line...
'Doc

2388. ant tuning question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-05 18:13:54 UTC
From: rb <rbigg@seii.net>
Message-ID: <aimeij$8kp$1@news.chatlink.com>
Source record: 137329

I asked this question on this list several years ago, intending to "do something" with it. However, other things interevened, and here I am several years later thinking "well, by golly, I guess now is a good time to get around to fixing my problem". Anyway, I have completely forgotten the answers to the quiz, so will try it again:

1. I have a 140' dipole

2. fed with ladderline

3. down to a 1:4 balun outside my window

4. Typical T match with roller coil as ant tuner (it's rated for 160m)

Background: the best I can do on antenna loading on 160m is with the coil all the way in (max L). Because of the length, the feedline Z presented to the tuner is reactive on 160m.

Assumption: feedline Z at tuner is too reactive on 160m for tuner because of flatop length

Solutions:

a. I can add ladderline to the feedline

b. I can add wire to the ends of my antenna (drooping downward, up to 20')

c. I can go to a 1:1 balun

Will going to a 1:1 balun help any in this situation?

Can adding feedline help?

Is adding wire to ant length likely to help?

Wou are quite correct and that is the way in most place.
I was seething at the time with another poster who had taken that
stance
on the thread.
It was in no way meant meant to be adressed to the whole group.
At that time I was certain that my past work was complete and correct
but when I was in the military you don't get along when marching and
leading with the left foot where other are leading with the right.If
you want to get along sometimes you have to grit and bear it or have
all the
xxxx kicked out of you.

> antenna idea, that maybe you should take another crack
> at it?
> 'Doc

Doc, I would put the whole computor program with values on this thread
but that would invite dismissal of what I have done by interjecting
programming skills. I made that mistake years ago so I am not anxious
to repeat it. What I have put out is from memory. The basic dimentions
are near enough
as is the capacitor values tho I admit I may have got the cpacitor
'ramp' direction backwards.
There is no doubt in my mind that the idea of merging two resonant
circuits
so that radiation at all frequencies uses ALL the physical length
required
and is always zero current at each end.
At present I have another wrinkle in that I have a virus in the
computor and until I find out how to shift the program to another
computor with out loosing the key. My disc at the present suggest that
there is no key on it !!!! What a mess I am in.
I have made many of these style antenna and also used them in arrays

and verticals e.t.c. as somebody else did in this town. A entrepreneur came to me with all finance required to start a company (He was a radio ham) after talking with me and the other ham on and off the air.
So there it is. I really can't see what the problem is on this thread. I have a loop that I have squashed down to an oblong shape and have retained the capacitor figures required for a loop with the range of 10-20 mHz.
This is clearly enunciated in the ARRL book as is the description of the basics as to what is happening. In that case the energy in the random radiator was that picked up by, in my case a dipole, and reradiating that frequency i.e. 20 meters.
The introduction of a loop antenna was able to change or remove a portion of that dipole such that it radiated at a frequency different to the 20 meter frequency that was origianly places upon it. Varying the capacitor on the squashed loop does just that, supplying me with varying frequencies that I would like to have(mixing produces F1 + F2= F3, F1 -F2 =F4) This to my mind is so basic .
I have placed it next to a 20 meter dipole, so close for best coupling that they have became one and then checked it out on the air to determine pattern changes and it did what I said, radiated the frequency aplied by the transmitter.
I may not have the best method of feed so let us get away from the feeding method or the impedance at the feed line. Frankly there are so few dimensions that could vary for optimisation that I am astonished again as I was years ago when I threw out every thing in disgust.
Its always possible that the antenna was affected by stray capacitance, the pig pen a mile away as many "new antennas turn out when newby clams are examined.
All I am asking for is my theoretical approach correct and if so what sort of
radiation patterns can it produces when optimised for a range. I can talk until
until I am blue in the face but until a 'name' or antenna guru comes along and looks at what I say by working at the basics I am not going to be able to convince anybody.

I am beginning to question my sanity but I am hanging in there, how long I can maintain this I don't know.
Regards
Art Unwin KB9MZ
Maybe I should leave for a couple of days to renew my self

I guess it depends on the condition of the material when you start and how much of a perfectionist you are. In this case, the "trouble" was less with my method than the armstrong method.

BTW, aluminum regardless of cleaning method oxidizes immediately upon contact with air which is why it doesn't solder or weld without special fluxes and/or inert gas shielding.

David, you did say 'theory.'

Visit your local library. Go to the technical/engineering section. Browse around the shelves or catalogue. Have a chat with the librarian. Choose an elementary book on radio engineering or, if you can find one, radio antennas. If it's a thick book go straight to the chapter on antennas. Sit down, make yourself comfortable, read, and enjoy.

Articles in amateur radio publications are nearly all about antenna construction.

Reg

I am thinking about getting one or a few hamsticks for mobile operations. Interesting to me sounds to operate during my commute times around 8am and 7pm PST. I like DX, so I would prefer an HF band that is closest to the MUFs. I was thinking that 20m would give me the best possibilities. Any thoughts?

Any thoughts on magnet mounts, are they safe?

Thanks
KU7T, Andreas

Hi All:

I remember from the "old days" there was a finish for aluminum called the
Drano finish.

It was done by soaking the metal part in hot water with Drano which is
mostly lye. After the lye treatment you could color the aluminum by putting
a dye like food coloring in boiling water and dropping in the part. which
forced the dye into the surface.

What it was a crude anodizing process. It creates a thick layer of aluminum
oxide on the surface
that is porous and the dye could be forced into.

Cleaning aluminum with lye should work and if you would like a sky blue
antenna it should be possible.

Here on the east coast, 17 meters is my preferred mobile band during the early morning and early evening hours. Pretty easy to work DX on SSB with good signal reports using my 17 meter hamstick. I use the magnet mount with three large magnets, sold by Lakeview for the Hamsticks. It hasn't budged a bit since installed on the top of my minivan. I also keep a 20 meter Hamstick in the van, and I use the Lakeview quick-release connectors so that I can change antennas in about 15 seconds.

Source record: 137339

This might be off-topic, but I'm going to put up a TV Antenna, and I have a question about the grounding. I plan to ground the pole itself to the main house electrical ground (outside). For this purpose I will use a 6 gauge wire. The RCA cable will go from the Antennna to a static-discharge-device. A 10 gauge wire will come off the static-discharge-unit. Do I have to run a separate wire all the way to the main ground for the static-discharge or can I just merge this wire with the main antenna pole ground?

If I do connect the static-discharge wire to the the main 6 gauge wire, does anyone have some weather proofing suggestions?

Thanks for your suggestions.

I use those green scotch pads that have no steel in them. You really
don't want to use steel wool on aluminum tubing as the small particles
imbed in the aluminum and then can later cause problems. "Rust", etc.

>

Good, you are fixing the real problem... it is a bit off frequency from the sound of it, probably influenced by your particular installation. Not at all to say it is your "fault", but the antenna sounds like it is loaded, so will be narrower than a full length dipole, and is influenced by proximity of objects (ground itself, support structures, feedline, metal in buildings etc).

> I expected some compromises with a shortened dipole. However, it
> would appear that the manufacturer's express assertion that this

Been a learning experience, hasn't it!

> however, that with some fiddling and ladder line, it can do the job.
> Had I known that from the outset, I still would have bought this
> antenna, but would have saved hours of testing and work.

If you have got the VSWR down to 1.5 (I assume on the tuner end of the cable at 80m, the VSWR at the antenna is 1.6, total cable loss is 0.6db, the tuner will be operating fairly efficiently (indeed you might not need it). You haven't told us what the antenna bandwidth is, but we might well expect <50KHz for VSWR<2.

If the desire to use ladder line is to operate over a wider bandwidth, why not just use a non resonant dipole. There is nothing magic about the gain of a resonant antenna (whether or not loaded), just convenient feedpoint impedance in certain lengths. Don't overlook the advantages of coax, convenient to route through a building, relatively unaffected by rain / dew / mist / snow / ice.

Anyway, "hours of testing and work" equates to valuable learning. With experience, you will solve these problems more quickly.

You have learn't something you can't learn from a book. Nevertheless, you might get interested and go back and read some texts on transmission lines to better understand what you were measuring, and how to use those measurements to guide you to the next steps.

Andreas,
I think 20 meters might be a good choice. Are
mag-mounts safe? That just depends on the size of
the antenna, the strength of the magnet(s), if you
ever 'hit' anything with the antenna, and how fast
you drive. So the 'best' answer is, probably.
'Doc

OK,
I guess I am not that much of a perfectionist, but don't tell my wife.
It'll shatter her image of me;<} I always wondered why the
manufacturers don't anodize antenna material. I work with anodized
architectural aluminum and it takes a long, long time for the local
conditions (southeastern WI) to corrode it. Usually it is a
dissimilar metals condition that corrodes it long before the
atmosphere can.

Hi Andreas,
I use them for 10,15 and 20 with three large magnets on a mount. They
work ok at those freqs and the big magnets hold on the freeway at 100
MPH, without a cross wind :<} Small trees are ok but drive thrus and
large trees are a no no. For those freqs they are a cheap
alternative,

I want to get a screwdriver and unless cost is a primary concern I
suggest you look at the screwdriver antennas that are out there. Do a
search on google of this group, there have been many discussions that
have included several of the makers and guys that have designed tuning
set ups that are IMHO pretty slick . Hope this helps.

BTW, if you get Hamsticks be careful cutting the stingers to length
:<{ the first time. Try to pick some up used, there are enough out
there.
Dan

There's certainly better alloys these days. I work in cable tv and the hardline and connectors used 20 years ago corroded many times faster than they do today. With todays products, corrosion of the aluminum itself is almost non-existent in comparison.

> the tuner is reactive on 160m.

Your 160m problems are virtually insolvable. Your feedpoint impedance on 160m
is about 10.7-j936 ohms yielding an SWR of more than 200:1 on 450 ohm ladder-
line. If your ladder-line length is around 83 feet, the impedance looking
into the transmission line is around 2 ohms. A 4:1 balun will attempt to
take that value down to 1/2 ohm. :-(A tuner trying to match 1/2 ohm
is extremely lossy.

IMO, the best thing you could do is short the ladder-line conductors at
the tuner and feed the antenna Marconi style against ground. Or you could
add some loading coils to your dipole.

20m-10m Hamsticks perform pretty well, i.e. their efficiency is
usually acceptable. 20m is often open when 17m is not. The MUF
seems to hover between 20m and 17m quite often. (or should I say
MUW for Maximum Useable Wavelength :-)

> Any thoughts on magnet mounts, are they safe?

The three or four magnet mounts work well with 20m-10m Hamsticks.
I use one when my screwdriver is off my pickup. The problem with
mag mounts on the lower frequency bands is that they don't offer
enough capacitance to ground.

Simplest one I can think of is a dipole. Strip the outer to leave only the inner conductor forming one half of the dipole, a choke "balun" is placed an equal distance down the intact part of the coax to form the other half of the dipole. This antenna can be quite effective used as a sloper or even just in a field day "damn I forgot the antenna" moment.

There was I believe a commercial 10/11m fibreglass antenna available some years ago using this very design. A nine-foot fibreglass tube with a piece of coax running up it and a large ferrite at the bottom. On top of that was a nine-foot whip, et voila, a vertical dipole.

One way to increase the performance of a Hamstick is to install a
base section under the antenna and use the next higher frequency
Hamstick. For instance, install a three foot section under a 17m
Hamstick and use it on 20m.

An explanation is hardly necessary. The outer coaxial conductor radiates by virtue of the current flowing on it and the voltage along its length, and the inner conductor does nothing except that it may form part of some impedance matching arrangement which can be accomplished in a less weighty and considerably more efficient manner by some other means.

On the other hand they do provide topics suitable for space-filling articles in amateur radio publications.

Although many years ago I was accustomed to reading ARRL and RSGB publications picked up at main-line railway station book stalls just to read on long rail journeys, eg., Kings Cross to Inverness, I am of the opinion that the RSGB has always presented the better quality elementary theoretical accompanyments to their construction articles.

Sadly, these days neither sort of publications are available from British railway station bookstalls.

On the other hand, American comics depicting Bill Holman's Smokey Stover, 'all that is foo is titters', Marzipan the Magician, Little Annie Oakly?, etc., may have been of lower quality print but were always more witty. I learned to read very early in life from American comics. Perhaps it explains my peculiar sense of humor (as a concession - the Yankee spelling).

Source record: 137360

I'll paraphrase what Walt Maxwell, W2DU says in his book _Reflections_:

The reflected power doesn't encounter a passive load equal to the source's impedance (which would result in absorption and dissipation of the reverse power). What it encounters is an active source feeding power outward toward the load. The interference between this outward going wave (actually, outward travelling V and I waves) and the returning reverse power results in a total re-reflection of the reverse power back toward the load.

For more detail, I highly recommend _Reflections_.

From: Greg Dukes <ka5get@charter.net>
Message-ID: <uku92itgre3jb0@corp.supernews.com>
Source record: 137363

Hello and thanks for the help.
I'm putting up a Cushcraft A3. This is an older model. The instructions say a coiled feed line choke made of 8 turns on a 6 inch form of RG-8 coax is needed at the feedpoint.
Is this needed or can I run my coax straight to the feedpoint without the feed line choke or a balun? If it is needed why?
If it is needed can I make a feed line choke of 8 turns on a 4 inch form instead of a 6 inch form and it still work?
Any other info ,suggestions or help will be greatly appreicated.

Source record: 137364

Ditto CAM's comment on the mismatch. Get rid of the 4:1 balun and go with a big 1:1 current balun. Centaur makes a good one. The 4:1 voltage balun is making your situation worse, not better, and it is very lossy at this kind of mismatch, probably over-heating too.

I use a 102 foot center-fed L with the top half horizotal at 60 feet high and the other half vertical. Feed with ladder line to a 1:1 balun to a short piece of coax to the shack. Tunes up on 160-10 with my Ameritron AT-30 tuner.

Changing the length of the feedline might help if it was 1/4 wave. It would act like a transformer but I will leave it to others in the group to explain how that works and if it might be of value to you. I am still trying to figure that out.

richardeford wrote:
"I have never understood why the reflected energy from a mismatched feeder / antenna isn`t re-absorbed at the TX, particularly if an atu ensures a 1:1 match from the TX output into the feeder."

There is a contradiction in the sentence above. A match between the TX output into the feeder is given and a mismatch between the feeder and the antenna is proposed.

This is possible in a lossy system but hardly the case in a near lossless system. There may be mismatches between antenna and/or transmitter and the surge impedances of the feedlines but a match from the TX output into the feeder is specified.

If the TX is matched to the feeder it is not because a 50-ohm transmitter is connected to 50-ohm coax. It is because the transmitter coax has the 1:1 SWR. I am assuming the "ATU" is remote and connected to the transmitter by coax. But the TX final amplifier would see no reflected signal were the "ATU" internal to the transmitter. When there is no SWR, there is no reflected energy to be "re-absorbed" at the TX.

Current flows from the transmitter into the output line becaust the transmitter voltage is higher than the output line voltage.

Best regards, Richard Harrison, KB5WZI

'Doc <w5lz@icok.net

SEZ:

> Probably your problem was the "big Nye Viking antenna tuner".
> They are known for being 'not the best' tuners around.
> 'Doc

Well Doc gotta disagree with that conclusion...

I've been using one of those "big Nye Viking antenna tuner" 's
with ladder line for over two years without suffering RFI in the shack.
I do use a piece of good coax to a balun in the basement and
ladder line to the feed point. Works well with no RFI to home equipment
at the 100 watt level and only a small amount, mostly to the VCR
and answering machine at the kilowatt level.

So tell me, where does this conclusion about the Nye-Viking
series of tuners come from? I asked the same question
many months ago on this very same newgroup with out a
single answer.

So what makes the N-V MBV-A a bad tuner?
is it:
A. Cost?
B. Inefficiency?
C. Other?

Really, I'm curious. The ARRL tests a couple of years ago
showed it to have some loss on 10 and 160, but overall
it came out OK compared to tuners in the same price
class. To be sure,it is expensive if new, but I got mine
at a nice used price.

Please educate me.

Thanks! Gary WG7X

Roy:

To understand and analyze the interaction between source feeding power and reflected power, you must use forward and reflected voltages and currents. An analysis with source and reflected voltages and currents illustrates what really happens. Total "power re-reflection" can only occur if a totally reflecting load is encountered. The reflected power arriving at the source almost never sees a load with an infinite SWR. As a result, a total re-reflection of power simply does not occur. A simple circuit analysis provides evidence of this. Wattmeter readings do not.

Source record: 137271

Wolfgang, OE1MWW, took the trouble to search around and advise me of two patents covering coils which resonated with their own turn-to-turn self-capacitance. Thank you Wolfgang. There are probably others.

> http://www.via.at/voxcom/04334228.pdf

Hiromi Matsumoto, Feb 2 1971. Tuned transformers. Coils wound on small ferrite bobbins. Extra turns wound between main coil turns but not participating in inductance - one end disconnected. Not directly related to antenna traps.

> http://www.via.at/voxcom/03560895.pdf

Robert H. Johns, Specifically for antenna traps. One layer of coil wound on top of the other rather than alongside.

Both patents are concerned with eliminating the tuning capacitor and minimising production costs.

Neither patent attempts to calculate inductance and, most important, to calculate equivalent lumped capacitance from coil dimensions. The manufacturer, in effect, is told to start winding and stop when the resonant frequency is reached. No attempt is made to predict the number of turns needed from dimensions.

Way back in the 1950's when I was designing wideband transmission measuring and other equipment to use coils which resonated with their own self-capacitance was one of a dozens of little designer tricks needed to make the equipment work. It was done without thinking about it. There was no time to think about patents. It never occurred to me. Or to the boss.

Why anyone should go to the trouble and great expense of patenting something which is shoved infront of everybody's eyes several times per week is beyond my imagination.

All my little program does is allow the number of turns to be approximately predicted before starting to wind the trap. Which is useful even if it's only 10 or 20 turns.

"Alodine" and "Irridite" are similar chromate processes that, when
applied to aluminum, result in a passivated, but conductive surface.
The latter was (maybe still?) used extensively by DB Products on
their aluminum antennas intended for hostile environments and the
former is commonly used to passivate cavities and RF components.
Neither process produces a "hard" surface, but both are suitable for
antenna protection. There is, of course, a cost consideration.

73,

Tom N4TAB

Hello Bob;

One more reply--

The RSGB book "HF Antenna Collection" has a chapter called 'Modelling and Testing' page 148, shows exactly what you are asking about. Figure 10 is your configuration, and the corner feed will give an excellent vertically polarized pattern at about a 25 degree takeoff angle. Good DX!

2433. FS: GEM QUAD PARTS

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-06 02:52:55 UTC
From: k1hjc@arrl.net
Message-ID: <12908d3f.0208051852.7bebb1fc@posting.google.com>
Source record: 137275

GEM QUAD spreaders, spider, tie rods, stainless steel clamps,
tension tubes, toroid balun and manual. Just add tie wraps and
wire to have 2-element 3 band (10-15-20) quad. $150.00 / BO.
Pickup only in Candia, New Hampshire.
E-mail me at K1HJC@ARRL.NET

2434. Re: Cleaning oxidized antenna

Newsgroup: rec.radio.amateur.antenna

Yes, anodizing puts a thick film of aluminum oxide on the surface. Aluminum oxide (alumina) is an excellent insulator -- in fact, it's used as a substrate for hybrid circuits and microstrip structures well into the microwave region. It's a hard, brittle ceramic among whose other common uses is sandpaper grit.

Aluminum oxide naturally forms on the surface of aluminum very quickly when it's exposed to air. It's this very thin and non-porous coating that protects it and prevents the chemically very active aluminum from corroding. The oxide is very thin because as soon as a very thin layer is formed, no more air can get to the underlying aluminum, so the oxide stops growing. Any kind of scratching or rubbing of the surface breaks this layer, which is why you can make electrical contact with the aluminum despite the insulating oxide on the surface.

With anodizing, you can make the oxide coating thick enough that it won't readily break, so you don't easily make contact with the underlying metal.

If one feeds an inv-L at the bottom how come the radial lengths
don't have to be the same length as the L part?
Like a dipole should be?

I picture it as a dipole with the ground being the other half of the
dipole. How does the ground know what its electrical length has
to be?

If I want to put radials under my lawn what it the best way
to cut a sliver into it for the radial?

Mark -

I am not aware of anyone who has tried a 40 meter quad in the configuration you are describing (except for possibly a few governments or commercial SW stations). 30 meters has been performed by Titanex (German engineering) with their TQ 6 2 element Quad. They provide 160, 80 and 40 from a dipole for their TQ 6-9
http://www.titanex.de/frames/quads.html

When you get to these wavelengths, the physical size becomes difficult to handle.
Like the Titanex TY 4030 Beam antenna
http://www.titanex.de/frames/beams.html

Rhombic or phased vertical arrays are more common in the 160, 80 and 40 meter bands, with phasing of the elements replacing the large mechanical rotating systems.
http://www.arraysolutions.com/

For example the set of Titanex V40 antennas
http://www.titanex.de/frames/verticals.html

with an Array Systems phasing array (This one is a three element, although 2 and 4 are also available)
http://www.arraysolutions.com/Products/trianglearray.htm#triangle%20top%20of%20page

and the W8AV Triangle plots
http://www.arraysolutions.com/Products/triangleplots.htm

Take jims advice! K.I.S.S. is the only way to go! While your at it, clean
and put anti-corosion stuff on the conectors then use some silly-cone RTV or
something the like to give a little WX protection.
Do try and support the ant. side of the coax as a strain relef so it won't
pull on the solder joints and other inner workings of the 259.

Source record: 137283

Richard Lord, GW3NCT wrote:
"---if energy is reflected back down the line, where does it go?"

Mostly, it bounces at the transmitter output or tuner output and joins new energy emerging from the transmitter for another go at the load.

The ATU loss is low and gives a match to the transmitter. Absence of SWR between transmitter and ATU is evidence of zero reflected energy as that is what makes standing waves. The reflection is at the load and travels the load feeder.

I am sorry my loss statement was unclear. In a lossless system with a conjugate match, you can slice it anywhere and looking in either direction you see the conjugate of the opposite direction. Loss tends to spoil this tidy arrangement.

Richard Lord wrote: "---if an atu ensures a 1:1 match from the TX output into the feeder."

As previously stated, "a 1:1 match from the TX---." guarantees no reflected power to the TX. The energy bounces are remote from the TX.

Richard Lord wrote: "But I am proposing that there IS reflected energy caused by the feedline/antenna mismatch.

The ATU simply bounces reflected energy back to the load. Some say an extremely high impedance is presented at the ATU output to the antenna circuit. Unless the impedance were not bidirectional, that high impedance would keep energy in the transmitter as well as preventing its return. Another explanation is part of the answer. The reflection is smaller than the wave which produces it. Flow is from higher to lower. To turn a reflection around, or any wave for that matter, it is necessary to invert the phase of either the voltage or current, but not both. To make a reflection into a re-reflection a circuit must perform this phase reversal. The ATU must handle that.

Best regards, Richard Harrison, KB5WZI

Don't bother to cut slits for the radials. Cut pieces of coat hanger into 6" pieces. Bend then in half. Next lay out the radial and use the bent pieces to stake the wire down. Kind of like stapling the wire to the ground. This will keep them out of the lawn mower and within a month you won't be able to find them as the grass covers them.

>V and current I.

For the typical narrow bandwidth (CW, SSB, RTTY, etc.) signals you can
use either reflected power or the impedance at the operating frequency
with equal accuracy.

But for wide band signals, such as FSTV, the line is not electrically
short for the _modulation_ frequencies, and reflected power does
matter. This happens when the reflections are significant compatred to
the period of the modulation waveform.

Using FSTV as a specific example, reflected power that is
subsequenctly re-reflected to the antenna causes time-delayed echoes,
manifested as a loss of video resolution or as ghost images, depending
on the length of the transmission line. A 200nsec long transmission
line produces a 400nsec delayed echo, which is enough to produce
noticeable loss of sharpness when the reflections are strong.

If you have ever used a TDR, then you can see that reflected signals
really DO exist. But for most amateur communications, they can be
handled adequately with a simpler frequency-domain model. FSTV and
other wide-band modes are the exception where the more complicated
time-domain model may be needed.

If the antenna tuner is properly tuned, it furnishes a Z0-match that re-routes all the reflected power (minus some tuner losses) back toward the antenna. Neglecting losses, the equation for a matched system on the antenna side of the tuner is:

forward power equals generated power plus reflected power

where, because of the match, all the generated power is delivered to the antenna.

> But I am proposing that there IS reflected energy caused by the
> feedline/antenna mismatch. Where does this reflected energy go when
> it reaches the ATU?

Most is re-routed back toward the antenna through a combination of re-reflection and destructive/constructive interference.

Richard Lord, GW3NCT wrote:
"---military TX are designed to be able to withstand double the normal output voltage."

Double the normal output voltage is what you get at the open-circuit end of a transmission line. There is another problem which requires wider spaces and better insulation aloft. Breakdown voltage of the atmosphere is reduced by lower pressure at high altitudes.

Perhaps this is a Opek UVS-300 antenna? Its a 3 section vertical that
is around 17 feet high. See http://www.comdac.com/opek/uvs.jpg

I've owned a couple of them but I will not make that mistake again.
I bought the second one because the dealer sold it to me below cost
(< $50) on the hope that I could fix the problem below. My readings
were worse.

A couple things to look for - look at the coil at the bottom of the antenna.
The solder connections are normally terrible and you'll likely
find some broken connections. I fixed a number of problems and got
great SWR on 440 band (and 220) but could never get the 2 meter stuff
very good.

Destructive/constructive interference is what happens with no-glare
picture glass. It is also what happens to make an antenna have gain
in certain directions and lack gain in other directions. It is also
what happens at the input of an antenna tuner in addition to the
actual re-reflection taking place. Both these processes are involved
in the re-directing of reflected power back toward the antenna. We have
a thread going now titled, "A Closer Look", which is in the process of
discussing these same concepts.

Which is proof that reflections exist. Heck, if reflections didn't
exist, we wouldn't be able to see ourselves in a mirror.

Source record: 137290

Unless you are playing games, Cecil, I see a length of 150-ohm line terminated in its Zo, so no reflections from the actual end load. But the coax sees a 3:1 SWR due to the mismatch at its termination: 150 +j0 ohms.

The mystery evidently is where does the power in the reflected wave come from and go to if it is present in the coax and not in the 150-ohm line - right?

I am probably missing the point, but what you have described is what I would expect.

The net delivered power to the final load is 75 watts via the lossless twinlead. You didn't specify, but I assume that the entire system is lossless. Thus, the source is required to deliver only 75 watts to the system.

There is a Zo match at the twinlead termination, hence no reflections. But the Zo mismatch at the coax termination results in a 3:1 SWR in the coax with the forward power in the coax (100 watts) less the reflected power (25) watts equaling the 75 watts passed on to the load by the twinlead. The 3:1 SWR demands forward and reflected powers in the coax section in the ratio measured.

The source is required to deliver only 75 watts to the system, which it does. It also would be required to dissipate the 25 watts of reflected power in the coax section - **unless** - the source is not matched to the 50 ohm coax and hence there is a plane of reflection at the junction of the source output and the coax input.

In that event, the mismatch would generate a re-reflection required to maintain the 100 watts forward power and 25 watts reflected power in the coax.

I vote for a mismatched source providing a reflection to account for the "circulating power" in the coax section. Depending upon the nature of the mismatch, the forward voltage and currents are combined at the source output with the reflected voltage and current in such a way as to produce a significant degree of re-reflection, if not total.

If the system is indeed lossless, only 75 watts is coming out of a lossless system to a real dissipative load, so Conservation of Energy requires only that the source deliver a net 75 watts to the system. Manifestations of forward and reflected power in the various line sections all add up, assuming your arithmetic and measurements are correct, to account for all power in the system.

An alternative view that appears to violate the C.of E. is that the source
is actually producing 100 watts of power, of which 75 watts is being
ultimately delivered to the load while the remaining 25 watts is being
circulated up and down the coax in the guise of reflected power - which
some folks will argue strenuously does not exist in the first place. <:}

But since that 25 watts is doing no work or being dissipated, then it
cannot really be coming from the source. Thus the source is required to
deliver only the 75 watts in the system that is being dissipated in a real
load. And the coax section enjoys an apparent 100 watts in the forward wave
and 25 watts in the reflected wave - exactly what happens in any coax
section with a 3:1 SWR occasioned by its termination.

An interesting thought experiment, Cecil.

Now that I have probably made a fool of myself, what didn't you tell us
that answers your question? <:}

There's no mystery so far. I started out with a simple example upon which
I think we can all agree. The Signal Generator has a built in resistor
which is absorbing all 25w of the reflected power.

Actually, the source is required to deliver the entire 100 watts of forward
power as the reflected power is being dissipated in a resistor.

> I vote for a mismatched source providing a reflection to account for the
> "circulating power" in the coax section.

Nope, it's not a ham transmitter. It is a signal generator designed to
dissipate all the reflected power. There is no re-reflection from the
source. This is to keep from muddying the waters.

Go up 30 / over 55 / down 24 back 55 at 6ft high then down 6 feet to form a loop . Feed at the start and finish points with some 450 ladder line as convenient . Stand the antenna tuner on a piece of insulation. Put a choke balun between ant. tuner and rig . Ignore earth. You'll be agreeably surprised on all bands

Heinrich,

Loaded dipoles can be troublsome (at least, they have been for me). Have you considered a folded dipole? At around 90' with low SWR from 1.8-30 mHz, that might be a better choice. I use mine for all my HF MARS work. Beats everything else I've tried. Needs to be fed in the center of the lower section with good 50-Ohm coax (RG-8/U or better), through a 4:1 balun (I used an old W2AU balun), and a high-wattage, non-inductive 600-Ohm termination in the center of the upper section (keep the conductors about 18" apart with PVC spreaders) and the feedline perpendicular to the antenna as much as possible and you should be in like Flint :-) I hang mine like an inverted-V (30-degrees) for a higher radiation angle than a flat-top. It's a reasonable compromise for local and DX contacts.

I have for sale 1 full size "HY-Gain" beam 10 meters. fully assembled for your inspection. 13' Boom and longest element is 22' $100.00 I also have a steel tower totaling 25'. this is in 3 sections 1 10 foot st8 and 1 5foot st8 and 1 10 foot top section. I don't not have a rotator. $50.00. pickup only from Nashua,NewHampshire. I am selling these because they are to big for my new QTH. This beam has spent a large portion of its life in storage. 73's Jeff AA1GR

2460. Antenna For Picking Up Marine Broadcasts Around 2 MHz: Suggestions, Pleae?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-10 11:45:53 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <aj2uhs$7hb$1@slb1.atl.mindspring.net>
Source record: 137302

Hello:

Am very interested in picking up some of the Marine broadcasts around 2 MHz
(e.g., the distress freq. at 2182, 2670, etc.)

Presently, have a very simple random-wire receive only antenna running
around 3 sides of my attic, then down to my receiver.

All I seem to pick up around 2 MHz is noise; higher freq's work reasonably
well.
Radio probably not a factor, as it's a new JRC NRD 545.

So, my guess is that my random wire is probably a miserable match for these
marine freq's.

Also, there is a strong possibility that a major part of my problem is that
I'm 25 miles or so from the water.
(I'm in a town due West by that distance from Boston harbor).
The marine transmissions are mainly, I'm told, SSB, so I "think" I should be
able to pick them up ?

Should I use a different antenna for these freq's? A simple vertical whip
type? Other?
If so, any suggestions would be most appreciated. (it has to fit reasonably
in my attic).

I'm really new at this, so please don't hesitate to make the suggestions,
and your thoughts on this, as detailed as
you can-really appreciate the help.

Much thanks,
Bob

Robert,
If you could extend your random wire so that it's
around 200 feet, or longer, it would probably help.
What would help even more is to get it as high as you
can get it. I would think most marine siganls are
vertically polarized, so a vertical may help (of course
if you could make it 120 feet tall, it'd be even nicer
but I wouldn't expect you could do that).
Depending on what you're listening for, there may
not be a lot of activity, not like it used to be.

how is 80m and 160m reception?

if you can pick up some comms on those bands you should be able to pick up
2Mhz marine channells. i dont think that theier is much activity on though

their are other marine bands to listen to also
try www.dxworld.com/utemarks.html for some sites that should list them

i live on long island and find i dont miss much because all i here is noise
on 2mhz most of the time (2.182Mhz)

VHF Marine and coast guard HF channels (5696 and 8983 plus weather on 6501)
all come through reasonably well, even on my handheld with a rubber duck

"Robert Rose"
> ...modes are used primarily in the
> range of 30 MHz to around 1.5 GHz?
> ...is SSB used for a lot of the others:

The most common modulation mode (from a bandwidth point of view) in that range is good old AM. It is used for the video part of non-digital TV (vestigial sideband actually), aircraft, and some military comms. TV audio and FM radio is wideband FM. Most common from a 'number of users' point of view would be narrow band FM (or equivalent phase modulation) used by mobile communications such as taxi, police, fire, boats, some military comms, etc. (some of these will be scambled these days, some will be 'trunked', and the military likes to frequency hop). The first 'cell phones' were nice clear FM, but they have now mainly switching to 'digital modes' and analog cell phones have been given a death sentence by the FCC (*). Digital modes are the fastest growing (digital TV, new cell phones).

Other than Amateurs, there's not very much SSB in that range.

Mike, I just modeled that antenna on 1.9 MHz. The maximum gain is -26dBi
compared to about 6 dBi for a 1/2WL dipole and the SWR on the coax at the
antenna is 16:1 giving additional losses. 33dB down from a 1/2WL dipole
is not an antenna that I would recommend for 160m operation.

I have used Reg's advice and his ENDFEED program recently and have been amazed at how effective a 11m by 11m Inverted-L (with only 12-- 5m radials and 300 ohm feed) is on 160-10m. On less than 50 watts on 160m I have worked Japan a few times and half my contacts are east of the Mississippi river. Additionally the Inverted-L gives you both a relatively low angle and a high angle lobe which acts like having two antennas and which ever dominates helps secure the contact. I have built one for portable use (6m by 6m) that does a great job 80-10m. ---Alan KB7MBI

'Doc wrote:
>
> CAM, Sounds reasonable so far... 'Doc

People are complaining that I didn't state the boundary conditions. Here are the assumptions: The signal generator outputs a constant 100 watts into 50 ohm coax and has the necessary circuitry built-in to route the reflected power to a resistor and dissipate all of the reflected power.

Assume there are no re-reflections from the source.

Assume there is no common-mode voltage/current.

Assume a lossless system except for the load and the resistor in the signal generator. The resistor in the signal generator and the load resistor(s) are being monitored to detect where the power goes.

V+ will represent forward voltage and V- will represent reflected voltage.
I+ will represent forward current and I- will represent reflected current.

Now we take the next step. o---150 ohm resistor
|
100w SigGen---50 ohm coax---+---1/2WL 150 ohm twinlead---o

o---50 ohm resistor

We can now switch loads from 150 ohms to 50 ohms. With the 150 ohm load switched in, there are three components, V+/I+ on the coax, V-/I- on the coax, and V+/I+ on the twinlead. V- and I- on the twinlead are zero.

Component #1: V+ on the coax is 70.7v, I+ on the coax is 1.414a
The impedance relationship is 70.7v/1.414a = 50 ohms
The power relationship is 70.7v * 1.414a = 100 watts

Component #2: V- on the coax is 35.36v, I+ on the coax is 0.707a
The impedance relationship is 35.36v/0.707a = 50 ohms
The power relationship is 35.36v * 0.707a = 25 watts

Component #3: V+ on the twinlead is 106.7v, I+ on the twinlead is 0.707a
The impedance relationship is 106.7v/0.707a = 150 ohms
The power relationship is 106.7v * 0.707a = 75 watts

Switch in the 50 ohm load.

Note that component #3 is exactly the same as one of the quantities that Steve adds to get a forward power of 133.33 watts on the twinlead after we switch in the 50 ohm load. The other quantity that Steve adds is 8.33 watts of re-reflected power. We will label that quantity Component #4.

********** Steve's treatment follows: **********

Component #4: Steve's re-reflected power of 8.33 watts.
Voltage is 35.35v, Current is 0.236a
The impedance relationship is 35.35v/0.236a = 150 ohms
The power relationship is 35.35v * 0.236a = 8.33 watts

Adding the voltages in Component #3 and Component #4
106.7v + 35.35v = 141.4v which is V+ on the twinlead with a 50 ohm load.

Adding the currents in Component #3 and Component #4
0.707a + 0.236a = 0.943a which is I+ on the twinlead with a 50 ohm load.

Component #5: ("supersum" of Component #3 and Component #4)
V+ on the twinlead is 141.4v, I+ on the twinlead is 0.943a
The impedance relationship is 141.4v/0.943a = 150 ohms
The power relationship is 141.4v * 0.943a = 133.33 watts

****

With the switch in the 150 ohm load position, the resistor in the signal generator is dissipating 25 watts and 75 watts is being dissipated in the 150 ohm load resistor. (Both are warm but the 150 ohm resistor load is warmer.)

With the switch in the 50 ohm load position, the resistor in the signal generator is dissipating zero watts and 100 watts is being dissipated in the 50 ohm load resistor. (The generator resistor is cold. The 50 ohm load resistor is warmer than the 150 ohm load resistor was before switching.)

It's pretty obvious that the same 25 watts that is dissipated in the generator resistor during 150 ohm load operation somehow makes it's way to the load after the 50 ohm load is switched in. How did that power get from the generator resistor to the load resistor with only the components listed above?

I'll just add to the replies you've already received since AM and FM have been discussed. USB is used from 144.000 - 144.300 and 50.000 - 50.300. There are some beacons in there and some CW stuff. I am not real familiar with the USB activity on 220mhz, 430mhz, 900mhz or above. You might want to check with the US Government Printing Office. I once obtained a wall poster of all frequency allocations.. quite large and it didn't cost a dime...

Source record: 137316

Over lunch in Washington with a couple of hams, one of which was a dear friend
N3CBW and another quite famous ham who gives propagation forcasts for a magazine, talked about antennas and my close friend related that I had just
demonstrated a new multiband antenna in his basement and a tired comment was made that such an antenna was badly needed in ham radio and then left the subject as if such a thing was impossible.(probably heard it to many times before)
In a later conversation with Mr Hately of E/H antenna fame he told me that he was not allowed to present a paper at a professional convention.
So he aproached a professor of a major university to review his work and got the retort that 'Antennas are the most widely discussed and investigated subject in the world and there is nothing 'new' to be found'.
Later I had a conversation with a professor in Illinois who is widely known for devising the log periodic antenna and he was my age and his discovery ws not that old.
So this begs the question. Can we safely rely on the present day books as being totally inclusive of the science such that if we memorise them we have every thing covered? Not knocking the excellent publications provided by the ARRL which I use all the time, I am looking at the prevailing attitudes on the subject.!
Years ago the U.S. government proposed closing the Patent office as every thing
that could be invented has now been noted!!
Can we really say that about antennas and thus clamp a heavy hand on experimentation and the future of the hobby?
Can we safely poo hoo any new future antenna break thru
with a possible impact of the Yagi on the hobby because it is not in the final book on antennas? Is this why there is hostility to those who continue to experiment with the 'new' such as Hately,Fractenna and commercial manufacturers
who try to push further the envelope of knowledge?
Po hooing makes an excellent discussion for a group on 80 metres as all can join in on the laughter, but does it help the hobby that has given all of us so much joy, that we hope we can pass on to future generations?
Think about the aproach we are taking by boo hoo ing new ideas and the lofty aproach that one must present it to experts for aproval before any discussion becomes worthwhile. We are just falling over each other to persuade possible new hams and the old to pursue the hobby of computors to the exclusion of amateur radio and stodgy thoughts as my

son did after getting his general license.

Think about it, comments are very welcome as I consider antennas to be part of the glue that holds us to this hobby. Even as important as SWR meters.

I have the manuals for both antennas."AR-10 and AR-6". I thought they gave the dimensions for the loops but I guess they don't. It's not really critical. Appx 9 inches dia will work for 10m. I would think the 6m version is appx 4-5 inches dia. It's not critical as you tap the middle area of the coil. If your dia varies a bit from theirs, it will just tap at a slightly different place.
I've made homebrew versions of both those antennas. MK

Hello CAM;

I've read a lot of material on the 'net written by people using antenna "modeling" software to tweak their designs before actually hanging them. While it sounds interesting, I've ever done it. I suppose if I had with this one, I might have never bothered erecting it, as your figures sound absolutly awful. I don't know what to say other than, with the exception of a couple of bands (7.4 mHz and 11.9 mHz - MARS bands - which require that I use my transmatch), the antenna as I described above works well, with an average indicated SWR at or below 1.5:1, drawing a minimum of 1.5 amps, up to nearly three. On the bands I mentioned above, the indicated SWR peaks about 2.5:1, but I believe that's caused by some of the junk (and there's a lot of that), which is in close proximity to the antenna.

My particular antenna is based on the design of the B&W BWD-1.8-30. Their's was too costly (way too costly), so I duplicated it as best I could. They claim a SWR of 2:1 at 1.8 mHz with the highest excursion above that frequency being 1.5:1 around maybe 25-25 mHz, by their chart. I've never been able to get figures like that without the transmatch switched in.

Anyhow, I wouldn't have suggested it to Heinrich as an alternative to the loaded dipole idea (I've never been able to get those things to work satisfactorily), unless I had wire hanging off the tower that was actually working. There could be many reasons my antenna works as well as it does.

With the exception of the balun, it's all homebrew, including the termination (B&W calls that a "balancing network"). Just a big old 600-Ohm dummy load in reality. Who knows? Antennas are queer birds. I know folks who can't get commercially-made antennas to work, but give them a spool of wire, a roll of ladder-line, a tape measure and a noise bridge, and they will do things that will simply amaze you. In my case, I think maybe I'm just working on dumb luck <grin>.

When you lay radials out on the ground, the ground detunes them. So
cutting them to exact lengths is generally a waste of time. Now, if
the radials were elevated off the ground, then yes, they need to be
resonant to work well.
>
> If I want to put radials under my lawn what it the best way

Does it self resonate anywhere?

Where do you feed it? Bottom or middle of L?

Can't use open wire at bottom can you?

Hi Mark,

This antenna began it's life as a CB antenna (AR-11, I think). A previous owner shortened the base section, trying for 29.6 mHz., I assume.

When I got hold of it, I "reconstructed" it according to the AR-6 dimensions, including the coax capacitor. As you mentioned, the Cushcraft manuals don't include the ring dimensions. I constructed three different rings: 8", 6", and 4". No matter which one I use, I end up with resonance between 52-54 mHz (I'm trying for 50.25 mHz center), with an XC of over 150-Ohms. The lowest SWR obtainable is always above 2:1, with the tuning arm set right at the radiator end of the ring.

I've been using RG-8/U coax to feed it, but I'm beginning to think it's perhaps decomposed somewhere along the run. I guess it's time to drag out the Cantenna. It's a shame when you can't trust new coax to really be "new".

Anyhow, thanks for the feedback. I wanted to make sure I was close to the right ring size before I tossed the feedline.

If a new antenna design is truly something that has not been developed before, is new technology, an improvement of science, then it will survive the peer review process and can be published in respected journals.

Art, for something revolutionary to happen, the existing laws of physics would have to be found wanting. The existing laws of physics are found wanting quite often, e.g. Einstein improved over Newton and apparently quantum physics is improving over Einstein. What is needed for a revolution in antennas is someone improving the existing accepted EM physics theories and implementing those improvements in reality.

Until someone can demonstrate that the accepted physics governing EM antennas is inadequate, most of us will continue to be skeptical of claims that lie outside that body of physics. Any new antenna that lies inside the present body of physics is not revolutionary and is merely evolutionary, by definition. There are, no doubt, some evolutionary antennas yet to be developed but they probably won't be a big deal.

Hi Art,

There is no mention of an LED. The diode is in the
constructive/destructive interference of the structure, built at
wavelength scales of the light transiting it, preventing light's
propagation in one direction.

Actually, describing as honeycomb goes a little beyond that, it is
like a stack of honeycombs (the general bulk of the structure).

Hi Peter,

Perhaps, but I am a EE and mechanical contraptions of mine never work.

I did develop a Rube Goldberg screwdriver tuning method. It consisted of
two telescoping AM automotive antennas mounted parallel side by side.
The ends were shorted together by a metal shorting block and connected
to a threaded shaft turned by a screwdriver motor. With this setup I
could continuously vary the length of that section of my transmission
line from two feet to six feet. That's about the time I came up with my
binary knife switch/relay switching method and realized that the
screwdriver motor part was redundant and too complicated.

I needed to vary the length of my ladder-line from zero to 25 feet.
If I had six of the above devices in series, I could do it all with
AM automotive antennas. How would that be for an antenna tuner?

Seriously, if anyone can think of a better way to vary the length
of the ladder-line other than knife switches or relays, I would
appreciate the input. Don't bother suggesting conductive bungie
cords - that's already been suggested.

Most multiband INVERTED-L antennas will be bottom fed. Although there are some advantaged to corner feeding it it is not a true Marconi and also is limited on the bands it can be used on, much like a doublet. Try to load up a 10m by 10m doublet on 160m. With an Inverted-L, like any antenna for multiband usage, resonance is not a factor. You use an ATU to match. Depending upon the bands you plan to use it on and the final dimensions you may be able to use an appropriate balun at the base of the inverted-L and run low loss coax back to the shack. My goal is to get a remote ATU and install it at the base of an Inverrted-L. I am by no means an antenna expert but a mere dabbler in the field...Alan KB7MBI

I don't know what you mean by self-tune. Do you mean auto-tuner built in?
Or do you mean that it has been designed to handle a high SWR? My SGC-500
amp spec says it will handle an SWR of 6:1. Unfortunately, a lot of power
can be lost if the amp eats the reflected power with an SWR of 6:1. Also
unfortunately, SWRs get a lot higher than 6:1 quite often.

Certainly is!

It helps to choose a time of year when the ground is soft and the grass is growing. If you really scalp the lawn with the mower before pegging down the radials, the radials are easier to lay and the grass will come back very quickly.

If the ground is a bit rough, leave a bit of slack in the wire as you staple it down. That will make it easier to stamp down any loops after few days (when your back is feeling better) and maybe pin them down with extra staples.

The argument has been happening under the title, "SWR, why isn't the energy re-absorbed at the TX". Steve is VE9SRB who contributed to that thread and earlier threads on the subject.

However, ignore Steve's arguments. With the example presented where, with a 150 ohm load, 75 watts reaches the load and 25w is dissipated in the signal generator, and switching to a 50 ohm load causes that 25 watts to be dissipated in the 50 ohm load instead of the signal generator, doesn't it stand to reason that the 25 watts was transported to the 50 ohm load by a combination of voltage and current in the 150 ohm environment?

2497. RFI problem witho Security System

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-10 17:29:59 UTC
From: Terry Sellick <tsellic@attglobal.net>
Message-ID: <3d5551f9_4@news1.prserv.net>
Source record: 137237

Hi all,

I am looking for some help in solving an RFI problem.

I have an ADT security system that sounds the alarm when I tune
up on 20m. It has 2 digital control stations. The alarm indicates
a "tamper alarm" on the control station closest to my GAP Challenger
antenna. I have disconnected the coax at the antenna, and connected
it to a dummy load at the antenna location. I can tune up without
causing any alarm. So it's the antenna radiation being picked up
in the house by one of the long security sensor cables, not a coax
problem, and not RF getting into the 110vac. The cables are 4
conductor unshielded.

ADT has been NO help in solving this. I have tried placing toroids
on both control panel cables, the security system power connection,
the security telephone connection, and all cables entering the security
panel box. I have grounded the security system box, and pcb to
the electrical ground which has an outside ground rod. I have
done all this one at a time to see if anything makes a difference. So far
no luck.

I don't know a lot about the control panels except that they feed back
digital signals to a security system box in the basement. Somehow,
RF is affecting the digital signal.

Has anyone solved this problem before? Any suggestions? My next plan
of attack is to get an RF Field Strength meter, and see if that will help
narrow down the location of the problem.

Thanks
Terry

(breakdown voltage of the atmosphere is reduced)."

You don`t need a tall mast, just a high altitude QTH. LaPaz, Bolivia is around 15,000 ft, and it`s down in a valley. I`ve worked with radios on the Altiplano above LaPaz.

A radio broadcast station high in the Andes near Quito, Ecuador was one of the first to use a quad loop antenna because of all the problems they had with corona from the tips of their dipole elements at high altitude.

Best regards, Richard Harrison, KB5WZI

I have conceptually tried it. Didn't come up with anything useful.
The wire on the reel would need to be shorted so the insulation
would have to be eliminated along with the spacers made out of
insulation. What I need to do is tuck those reels into a different
dimension from the ones the feedline is in.

What kind of material in your toroids? How many turns? Ten turns
on an 'F' material toroid works wonders for me.

There is I believe, a rec radio group that that discuss old military
radios.
There is also a large store on the west coast that deals extensively
in military radios and parts. On the antenna question since you are
using it as a receiver I
would match the radio to the impedance supplied to it by a random long
wire
Low parts number circuits are readily made to put it front of the
first R.F. amplifier.I renewed a HRO 50-T1 and was relly surprised how
component values had wandered which require replacement of all
capacitors and resisters, especialy the capacitors in the tuning
circuit that control temperature drift. In your case I would also
remove the 6146 output tubes and isolate the HV line.
Story.
My last purchase of a radio to mess with was at an auction that
described it as a radio transmitter, removed after a trial run tests
of a nuclear submarine
for minor adjustments. As it was listed as weighing 200# it came to
mind that here was a 'state of the art' radio with circuits similar to
those suggested by Wes Hayward and others. The bidding was spirited
which reinforced my thoughts and I purchased it for $1000 I believe.
My wife and I used the opportunity to take a leisurely 3 day drive in
an old 300D to get to the east coast to where it sat.
On arrival to pick it up I became a 'basket case'. First the
tranceiver was a
valve/tube job (protection against nuclear damage as shown with solid
state
devices.) The other shock was instead of weighing 200# it was 2000#
shaped like a steel cupboard. I did get it home but my wife was close
to losing it because of my driving speed. It still stands in one of my
garages after getting massive help from some who could not disappear

quick enough. Undoubtedly on my demise it will finish up in the junk yard and good luck to those who have to get it there.
I have a hernia now but I am not sure that the events can be coupled.
I don't mess with radios anymore. As an aside, the treasured HRO 50 fell off a
truck while in the process of moving house.
Good luck with the project
Art KB9MZ

Hello Tom,
Of course it is "possible". If random length wire antennas are useful than most any "configuration" will radiate and basically "get you on the air" even if the swr is 3:1 you'll do fine.

There is IMHO way too much "antenna analysis" and "religious philosophy" about Ham Radio antennas and which ones are better than others. While there are measurable differences between antenna types and overall designs I have done well with a W9INN 5-band (80,40,20,15,10) resonant dipole at 54 ft above ground. Last DXCC check shows me at 311 countries..all on a simple dipole.

Also IMHO (and not to toot my own horn) what - is - important (and totally free to everyone that pursues it) is "operator skill" especially in DX plie-ups. Many times those ops with 200 ft towers and "legal limit power" (or more!) and stacked mono-banders have to wait till I get done with my DX qso (on a dipole!) before they can call. Also being at 5412 ft above sea level helps too!!!

2504. Homebrew mobile antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-10 18:57:48 UTC
From: Denis O' Flynn <denisf@eircom.net>
Message-ID: <_ee59.8055$zX3.11251@news.indigo.ie>
Source record: 137251

Anyone got any ideas for a homebrew mobile antenna. I plan to use the
Icom -706 MKII rig and would like to use down to 80m.

Many thanks in anticipation
de

Art Unwin wrote:
"---a tired comment was made that such an antenna (a new multiband antenna) was badly needed in ham radio and then left the subject as if such a thing was impossible---."

If antenna development had kept pace with electronics during the past 50 years, a near d-c to daylight radiator would fit in the palm of your hand, have continuously selectable directivity from a 2-degree spot to isotropic, have 95% efficiency, accept a kilowatt continuous power without degradation, and present a flat 50-ohm resistance to the source over the entire spectrum. It would readily radiate, of course.

Antenna performance is far short of ideal, so don`t close the patent office just yet.

Best regards, Richard Harrison, KB5WZI

Chuckie Boy is fantasizing again.

| There is IMHO way too much "antenna analysis" and "religious
|philosophy" about Ham Radio antennas and which ones are better than
|others.

Since this an amateur radio discussion group about antennas, what the
hell do you expect here? If it's too much for you, leave.

|While there are measurable differences between antenna types
|and overall designs

Why I didn't know that, thanks for pointing it out.

|I have done well with a W9INN 5-band
|(80,40,20,15,10) resonant dipole at 54 ft above ground.

Here we go again with the shilling for a so-so commercial product.

| Also IMHO (and not to toot my own horn)

Then whose horn are you tooting, Chuckie? Uh oh I forgot, W9INN's.

|what - is - important (and
|totally free to everyone that pursues it) is "operator skill" especially
|in DX plie-ups. Many times those ops with 200 ft towers and "legal
|limit power" (or more!) and stacked mono-banders have to wait till I get
|done with my DX qso (on a dipole!) before they can call.

Right, they're two hours away from the band opening at their location.
BTW, if you quit relying on that DXcluster crutch, you could find the
DX first and work them before the pileup starts.

| Also being at
|5412 ft above sea level helps too!!!

You make a lot of absurd statements, but this one is tops. I guess
you must do a lot better than those guys down on the beach who just
have all of that nasty old sea water for a horizon.

BTW, is that 5412 feet elevation at ground level or at the antenna
height? We need to be precise, as I'm sure it makes a difference.

Thanks for the nice usenet post.

Tom,
It will work, just not very well. The 'legs'
of the antenna are too close together. The
input impedance is going to be some rediculous
value that a tuner may not even be able to handle.
Not knowing what the area you have to play with
looks like, I can't even guess at a good alternative.
Sorry 'bout that...

Heinrich wrote:
"---I only have room for an antenna of about 130 feet overall."

A 130 ft folded dipole is 1/2-wave of wire and resonates at 160m.
Response is less than 1 db poorer than a full size 1/2-wave dipole.
Problem with the 1/4-wave folded dipole is that its drivepoint impedance
is about 6000 ohms. Don`t use coax to feed this, Use the highest
impedance balanced line you can afford, 600-ohm, 450-ohm, or 300-ohm.
Bandwidth is only 5%, so you need a tuner to cover twice that bandwidth
at 160m. Don`t use that loading resistor opposite the feedline. It`s a
loser.

Best regards, Richard Harrison, KB5WZI

joules/sec.

The law of conservation of energy requires that the total power dissipated in the entire system be equal to the total power delivered to the system AND that the power flowing into a node or junction be equal to the power flowing out of the junction + the power dissipated at (in) the junction. These are the issues to consider relative to the conservation of energy.

The addition of forward voltages and the fact the resulting total forward power exceeds the added power in the two individual voltages when considered independently in the line does not violate the law of conservation of energy.

You are incorrectly trying to interweave two concepts.

Steve

> The impedance relationship is 141.4v/0.943a = 150 ohms
> The power relationship is 141.4v * 0.943a = 133.33 watts
>
> **

Let's get a couple more components.

Component #6: reflected from the right-hand junction (computed from
component 5 and reflection coefficients at the junction)
V- on the twinlead is 70.7v, I- on the twinlead is 0.472a
The impedance relationship is 70.7v/0.472 = 150 ohms
The power relationship is 70.7v*0.472 = 33.33 watts

Component #7: transmitted on to the load (computed from component 5
and transmission coefficients at the right-hand junction)
V+ on the coax is 70.7v, I+ on the coax is 1.414a
The impedance relationship is 70.7v/1.414 = 50 ohms
The power relationship is 70.7v*1.414 = 100.0 watts

Now components #6 and #7 make sense and agree with your results. Note
that component #7 exists because the right-hand junction is not an
open-circuit or a short-circuit, i.e., it doesn't cause a complete
reflection of the V and I waves. Since that's true for the right-hand
junction, it's also true for the left-hand junction. Let's do one more
component:

Component #8: transmitted on to the source (computed from component 6
and transmission coefficients at the left-hand junction)
V- on the coax is 35.35v, I- on the coax is 0.707a
The impedance relationship is 35.35/0.707 = 50 ohms
The power relationship is 35.35*0.707 = 25.0 watts

If you agree that part of component #5 is transmitted on toward the
load, then you should have no disagreement that part of component #6
is transmitted on toward the source.

Now in general each reflection or transmission coefficient is a
complex quantity and has a phase associated with it. For the simple
example, the V reflection coefficient is either 0.5 (0 degrees) or
-0.5 (180 degrees). If you assign 0 degrees phase to both V and I of
component 1 and then track the phases all the way through, I think you
will find that V- for component #8 is 180 degrees out of phase with V-
for component #2. Likewise, I- for component #8 is 180 degrees out of
phase with I- for component #2. The V- waves cancel and the I- waves
cancel.

> components listed above?

I didn't slog through all the math to verify my suspicion that the source-traveling waves are actually 180 degrees out of phase with each other, but it's a safe bet that they are. You've already told me that the generator resistor is cold. 73,

Bill N3WK

You have to be quite careful what you mean by "improving over".

For a huge range of everyday situations, Einstein's equations simplify down to good old Newtonian mechanics, because the relativistic terms for those situations are negligible. The "improvements" that Einstein made were to identify the limits where Newtonian mechanics start to become inaccurate, and explain those using his new theory. But inside those limits, Einstein actually *confirmed* Newton's laws of motion.

Much the same relationship holds between Maxwell's equations, which are deeply rooted in classical physics, and more modern approaches such as quantum electrodynamics. The modern approaches actually *confirm* where Maxwell's equations still hold good - and that certainly includes radio antennas.

That's probably what Art's professors meant by "Everything is now known about antennas." That's a fair viewpoint, because Maxwell had the basic science all nailed down before radio and antennas were even invented!

Antenna engineering is all about finding new ways of using the existing basic science.

>Until someone can demonstrate that the accepted physics governing EM
>antennas is inadequate, most of us will continue to be skeptical of
>claims that lie outside that body of physics.

That skepticism is very well justified, given the millions of antennas that do work according to accepted physics.

It's worth noting that even the CFA is not claiming to be totally new science - it's only claiming to be a new way of interpreting Maxwell's equations, and building a device to use this new interpretation. The counter-argument is that it isn't a valid interpretation, and therefore the CFA can't work; and the more reliable measurements confirm that indeed it doesn't.

>Any new antenna that lies inside the present body of physics is not
>revolutionary and is merely evolutionary, by definition. There are, no
>doubt, some evolutionary antennas yet to be developed but they probably
>won't be a big deal.

Well, no big deal if you're determined not to be impressed. Fortunately there are still plenty of clever things to be done. Come on, surprise us... just don't pretend it's new physics.

>If one feeds an inv-L at the bottom how come the radial lengths
>don't have to be the same length as the L part?
>Like a dipole should be?

Because the radials are not the only thin involved.

>I picture it as a dipole with the ground being the other half of the
>dipole.

That picture is misleading. It's only accurate when the ground is not a significant part of the antenna system, as in the classic 'ground plane' antenna.

Think of "the ground" as being a lossy reflector that is very, very large compared to a wavelength. The purpose of the radials is to make a better (lower loss) 'connection' to the ground than can be had with a simple ground rod.

The questions of how many radials, how long, etc., have been argued for a very long time. For most amateur applications, the answers are 'as many as you can put down' and "as long as you can get them,

>How does the ground know what its electrical length has
>to be?

Makes no difference. It's just a very big conducting sheet.

>Anyone got any ideas for a homebrew mobile antenna. I plan to use the
>Icom -706 MKII rig and would like to use down to 80m.

Hi Denis, A homebrew multiband mobile antenna is difficult, or it was for me. The "screwdriver" style antenna is by far the easiest in terms of changing bands. If I were buying a mobile antenna, a screwdriver would be my choice. I haven't homebrewed one so I can't comment on the difficulity. I haven't seen any DIY plans either. Also, base loading, especially on 80 and 40 is not the best method.
What I did, since I wanted to homebrew the "best", as far as efficiency, was build a "bugcatcher" style.
It is center loaded, with interchangable loading coils for each band, and matching networks at the base for each band. I also use a capacity hat at the very top that I change for each band. The antenna is 8' long, uses 1" fibreglass tubing for the bottom, and 1/4" rod for the top. The homebrew loading coils plug in with banana plugs and jacks. Hope you get the idea. I you would like more details, let me know.

Can anyone speak about the accuracy of an Eznec(v3.0.42) model of an antenna over "real" ground?

I have a wire 2 element yagi for 20 meters, where the driven element is at 30 feet, and the reflector at only 23 feet. Are the Eznec plots over "real, high accuracy ground" for a model of this going to be as accurate as if both elements are at the same height? (Assume the other dimensions of the yagi do not change, only the rotation or "tilt" of the boom)

Is such a model a good approximation for the same yagi over sloped ground? (I would guess no, because I would speculate that the sloped ground would screw around with the ground reflection angles...plus what else?)

Thanks,

"Art Unwin KB9MZ" quoted some dumb bunny...
> "...there is nothing 'new' to be found."

Yeah right...

Switch mode antennas

A radiator interspersed with numerous optically-controlled switches. The switches are something like (?) especially-designed ultrahigh speed FET switches where the gate is fed by a thin strand of 'fiber optic' fiber carrying pulses of light that control the on/off state of each switch. The antenna element would have many such switches and many fibers running down to the control system. The control system would have to be predictive (obviously). Trivial.

The basic idea is that the electrical length of the antenna element could be dynamically controlled.

By using "switch mode power supply" and "power factor correction" techniques, even the input impedance could be controlled. That's a neat trick !

When using a long element and a very short burst of very high frequency RF (so that the wavelength is much shorter than the element), the pulse of RF could even be trapped and its reflections controlled until it had finished radiating. Not much good for most applications, but who knows ? Maybe Ultra Wideband (UWB) radar ?

Yes, I know that the processing and control would have to be very fast - much faster than the RF itself. What are the chances that technology in that realm would advance ? ;-)

A good name for this technology might be the "Joint Tactical Antenna Project".

:-)

How do you keep the spacing between wires when the wind blows?

> independently in the line does not violate the law of conservation of
> energy.

Why not, Steve? Assume you have two 200 watt signals of 100 volts at
2 amps each. You say you can add them to get 400 volts at 4 amps. Why
is that not a violation of the conservation of energy principle?

In your example, you are adding 106.07v at 0.707a (75w) to 35.35v at
0.236a (8.33w) to get 141.4v at 0.943a (133.33w). Why is that not
the same thing as above?

> You are incorrectly trying to interweave two concepts.

Nope, I'm not. The concept is a common one among the engineers who manage
the longest transmission lines in the world. The following configurations
use a signal generator with built in circuitry that dissipates all of the
reflected power so there is zero power re-reflected from the source. The
lines are lossless and there are no common mode components. Please answer
the following question.

Configuration #1

100w source---50 ohm line---+---1/2WL 150 ohm line---150 ohm load

The source is dissipating 25 watts of reflected power. The 150 ohm load
is dissipating 75 watts of power. The forward voltage on the 150 ohm line
is 106.7 volts and the forward current current is 0.707a (75w).

Configuration #2

100w source---50 ohm line---+---1/2WL 150 ohm line---50 ohm load

The source is dissipating zero watts of reflected power. The 50 ohm
load is dissipating 100 watts of power. According to you, only 8.33w
have been added to the 75w in Configuration #1 to increase the forward
voltage on the 150 ohm line to 141.4v and the current to 0.943a.

The question is: How does the 25 watts being dissipated in Configuration
#1 make it to the load in Configuration #2 without becoming part of the
forward voltage and forward current on the 150 ohm line?

> knife switches or relays, I would appreciate
> the input.

String your adjustable length of 'open wire' between two fixed structures - pull it tight so that it won't move in the wind. Build a boogie contraption that will roll back and forth along the wires and provide contact with the individual wires. A jumper of appropriate twin lead connects from the boogie to your shack. The boogie is pulled back and forth with rope and pulleys. A motor and computer control is a trivial addition.

There will be a difference in the operation since you will have an unterminated end on your adjustable length section. I suspect that it would still work.

--

If I were you, I would use big nasty relays with husky silver contacts. I think that they are called 'contactors' in the electrical trade. The ones that I have seen look like they would be perfectly suitable to switching high power in the HF range.

Cecil, I understand where you are coming from but to have a reflex
action
that any idea will not work is not good for the hobby. 73 magazine was
tremendously succesful when it printed different antenna designs some
of which may had dubious claims but it would appear that many hams are
still interested in those who try to find the perfect antenna. In my
case I and my family in the U.K. and aussie land helped me to the tune
of several thousand dollars in my endeaver.
After I obtained a patent I went to my peers which was this thread to
discuss it.
As you know I was poo hoo'd a few years ago same as I am being now.
Some say building a good product and every one will come running.
If you have the money to go all the way over a length of time you will
surely be attacked by those on this group who I consider experts.
Fractenna was blasted
because his was a 'new' idea yet all forgot what possible advantages
it presented.But this thread did attempt to supply reasons based on
known theory
to debunk statements made by some. Same with Hately and others, an
endless stream of reasons backed by solid physics why it couln't work.
In my case no one has debunked the basic theory. None have shown that
in the physics world it cannot meet claims. Even in the poll none of
the known experts
has entered an opinion. Is it because they don't know and cannot

refute my claims or frightened to give what eventualy may be proved incorrect.
Nobody has denounced me as a fraud or guilty of ignoring the laws of physics.
Who among you can clearly describe what happens when two resonant members
are placed close to each other with clarity and based on the laws of physics?
Ofcourse I am possesive of the antenna despite the statement of one person
that I must prove all to him. This is an antenna discussion group populated
by many clever people who give much of them selves to the hobby and to which I came to discuss that what I had worked on for several years.
All I asked for was for an explanation of why the antenna could give me so many advantages over the norm but all minds are closed. Even yourself stated that 'anything new will not amount to much'.
Fortunately two experts have come forward with no pre-ordained ideas to examine the basics of the antenna which I will share with all regardless whether they are positive or negative. I also know that no one MUST supply an answer, but if they chose to do so I would expect an answer that matches known physics. If an expert voted negatively or positively I would have a link as to why.Is it good for me, no.
Is it good for ham radio, No. Is expementation to be squashed because all is known..No. Should we strike at the messenger because of what he holds in his hands?Apparently yes.Who is the first person who will come forward to refute that two resonant circuits when placed close to each other cannot produce
a quarsi collinear radiation pattern based on solid physics? Am I as a member of the ham fraternity not worthy to present such a question. Am I as a ham allowed to refute statements in the handbook that bases collinear gain on the clearance
between dipoles instead of the distance between current maxima or must I be a name to make such challenges? Am I going to be trashed based on opinion that has no basis in physics. So again I say why are we all so antagonistic and opinionated before the fact when seeing results of experiments, I challenged all
to examine what I offered with the hope that I would be corrected in my
thoughts based on physics, so why are all, experts or otherwise, refraining to supply facts that refute what I claim? Most have done so in the past on other
innovators yet somehow all are timid on the subject of two resonant circuits
co joined.
Why don't you Cecil, who is knowledgable in the antenna arts, start the ball rolling as to what happens or can happen when the two circuits are co-joined with respect to radiation ?
Please, Pretty please.... If you do, then maybe other knowlegable people will comment if only to refute what you have said which they

often do.
Let's face it, I obtained a patent,I and others have reproduced what I claimed.
The University of Illinois confirmed my results. I placed an explanation on the web via a page, I have stated links in antenna books that seemingly confirm the
physics aspect.So I have done as much as I can do prior to presenting it here. What else can I do to offer for debate on this thread populated by many antenna experts. How many hoops do I have to jump thru or how many thousands of dollars more do I have to spend to get the attention of my peers?

Warmest regards
Art Unwin KB9MZ

I suspect sporadic fighting will now occur.
Yes the sporatics are at it again, beware Punchinello

It tries to be transmitted on toward the source but doesn't make it
because of destructive interference which you call cancellation.

> Now in general each reflection or transmission coefficient is a
> complex quantity and has a phase associated with it. For the simple

> for component #2. Likewise, I- for component #8 is 180 degrees out of
> phase with I- for component #2. The V- waves cancel and the I- waves
> cancel.

Yes, yes, yes. That is exactly what I have been saying and your components agree perfectly with the phasor diagram that I published on my web page a year or so ago. Steve is not including those cancelled voltages in his voltage equation and those cancelled voltages are what furnish the energy foundation for the forward wave on the 150 ohm line.

As I said before, the complete power equation is:

75w + 8.33w + 25w + 25w = 133.3w (Steve said it was 75w + 8.33w = 133.33w)

or:

106.066v^2/150 + 35.355v^2/150 + 35.355v^2/50 + (-35.355)^2/50 = 141.4^2/150

The complete voltage equation is:

106.066v + 35.355v + 35.355v - 35.355v = 141.4v where:

106.066v^2/150 = 75w from Component #3
35.355v^2/150 = 8.33w from Component #4
35.355v^2/50 = 25w from Component #2
(-35.355^2/50) = 25w from Component #8

As you say, Component #2 and Component #8 cancel, i.e. engage in destructive interference. The constructive interference power heads back toward the load.

Thanks Bill, it seems that we are essentially in agreement. The voltage equation balances and the power equation balances.

That unterminated end will act as a stub and change the tuning. I don't
need another variable in the equation. It might help on some bands but
probably hurt on other bands.

I've already done that, Art, years ago. When I was in Arizona, I
designed a quad that had only one driven element, thus solving the
multiple loop or multiple feedline problems with multi-band quads.
The driven element was a full-wave loop on 17m. I had three resonant
reflectors and the two-element quad worked well on 20m, 17m, and 15m.
It was fed with ladder-line. There's nothing new about mutual
coupling. I haven't been closely following your particular configuration
but it sounded like you had a non-resonant length driven element and
a resonant parasitic element just as I did above. Is that right?

Bob wrote:
"I`m in a town due West of Boston by that distance (25 mi.) from Boston harbor."

I was going to recommend a Beverage antenna until Bob wrote that the antenna had to fit his attic.

Use a vertically polartzed loop. Stand the plane of the loop vertical and aligned with the desired direction. Wind a few turns of good size wire on a large form as required to tune the desired frequency range with whatever variable capacitor you can come up with. An extra turn can be added to the loop for coupling to your receiver.

Reg Edwards, G4FGQ has nice free programs you can download to optimize your loop.

A loop can improve signal to noise by its directionaliy and frequency selectivity. It should improve reception significantly over a random wire. You probably will want it alongside the radio for tuning convenience unless your interest is only in one channel.

Most maritime traffic has moved to 150 MHz VHF and microwave satellite channels.

Best regards, Richard Harrison, KB5WZI

Hello! I am intending to get my license, however I am worried about one thing. I live in a 'mobile home community' (trailer park, for the non-euphemistic :) I have a yard about 45 x 50 and 1 tree. I really dont think they are going to appreciate me if I erect some huge yagi thats 60' tall and almost bigger than my home, and yet I dont want to be limited to talking local, I would like a range of 1000 miles at least. Do I have any options? Will a good 'stealthy' dipole do this for me?
Thanks

> not be a lot of activity, not like it used to be.

Many...not all... of the shipping lines have totally removed HF from their ships. President lines I know has removed it all and relies now on a satellite device that feeds both voice and data. The only radio, in the traditional sense, on the ship is the VHF that they are required to have on the bridge and a loop device under decks that operates on 440 and allows the crew to communicate from anywhere on the ship. The radio room, which used to be manned, now contains a rack of network gear and no people.

Rick

> able to pick them up ?
>
Yes, if there are ssb signals on the air on those freqs you should
definitely be hearing them with your attic wire antenna - and with
much lesser antennas at those distances for that matter. I suspect
that the reason you're not hearing marine ops on those freqs is
because they simply are not there. Harbor and coastal marine ops are
normally conducted in the VHF FM marine band, not on the 2-30mHz MF/HF
high-seas marine freqs. The 545 won't tune VHF freqs without it's
(overpriced!) optional VHF converter but just about any scanner will
tune those freqs. The following provides the VHF freqs.

http://www.noftc.com/Marine%20Frequencies.htm

One other factor is in play here. During the summer months the natural
noise level on 2 mHz is usually bordering on deafening which renders
that portion of the spectrum close to useless. I suggest that you tune

around 3.8 mHz LSB for 75m ham stations after sundown when the noise
level drops as a test of your "receiving station". You should hear
gobs of hams yakking if the antenna & rcvr are working OK. If you hear
the hams your antenna & radio are fine and your problem with not
hearing any 2.6 mHz marine signals is because there ain't none.
>
>

>
>
Transmiting antennas are one side of the coin but for your purposes as
an SWL any "better antenna designs" won't make any noticeable
differences at all, leave it alone and start tuning. For a short list
of MF/HF marine freqs:

Hi Bob, me again.

I haven't heard a marine signal on the 2 MHz band in many years...some folks say that 2182 is still active as a distress freq but I've never caught anything there.

You have all kinds of options. A vertical can be put up and that will take up very little space. It might not be the best antenna but you should be able to make many contacts with it. Even a simple wire dipole will work for lots of fun.

> 'Doc

You are so right doc,Ibut is it unreasonable to ask for structured
answers?
Many will suggest that I write it up even tho i have given talks at
hamfests
including one sponsered by the arrl Looking over my recent e mail on
this discussion I came across one from a known ,kind and polite
gentleman with tremendous credentials in the field. He suggested that
the next hoop I should jump thru was to attend a community college and
take classes in effective communication and then consider writing it
up.....seems reasonable.
In my working career with G.E. a senior vice president suggested to
the manager
of the plant that I worked ,that I would be more effective to GE if my
talents
was used as a technical writer instead of a senior engineer. At that
time a 100 engineers were laid off and I was one of the remaining five
so I can assume his statement was not based on lack of engineering
talent (just a statement, I am not blowing my horn)
The ravages of time and illnesses together with a wonky keyboard
changes all as we get older, as all can see. But even if I take the
given advice the odds are the ARRL will refuse it according to the
many complaints I've heard. Heck I can't even get it past this group
and since I am getting out of my sixties I will probably be dead
before I could even see the light at the end of the tunnel! So give me
a break guys,s some invested good money based on my thought
and I need to explain to them why I was wrong. Also why I refused a
entreprenuers offer to totally finance it because I wanted to be sure
that my claims were solid and ethical where many manufacturers were
otherwise.
This is not about money now, it is about reaching finality in what I
still believe is a very viable antenna of which I have made many. So
cut me some slack guys, look at what I have shown you, the patents,
the clear descriptions in the Arrl book for associated resonant
antennas that I alluded to e.t.c.Plus
a good look at the associated physics on which you base your

conclusions so that we all can debate the plusses and negs or where the experts say that I have wandered from theories accepted in academia. Yes, I am being personal with this antenna but I want to share it with all because I firmly believe in it. Please don't give me another hoop to jump thru.
Best regards

Art, KB9MZ wrote:
"Who among you can clearly describe what happens when two resonant members are placed close to each other with clarity and based on the laws of physics?"

That is the proponent`s job, Art.

The dipole and loop are coupled, Art has implied. The loop is the feed mechanism we have been told. If so, the dipole and loop have a mutual impedance. This can be determined as a voltage to current ratio (Ohm`s law) by measuring the current in one member caused by voltage across the other member, or vice versa.

This is textbook stuff. you can determine a coefficient of coupling, etc. but if you have an antenna, measurement takes the place of prediction. See if you have a double humped response and whether it comes from stagger tuning, overcoupling, or both.

It is, unfortunately perhaps, up to the proponent of a novelty to make the case for it, unless the world knows it is desperate for the novelty and makes a grab for it as a drowning man might grasp for a straw.

Best regards, Richard Harrison, KB5WZI

Eznec is much more than accurate enough for all purposes it is used for.

Regarding the influence of the ground there is not much point in having a program more accurate than you know the resistivity, permittivity and depth of the soil in your back yard at 60 Hz, which is probably worse than plus or minus 50%.

And what the ground might be at 14 MHz is anybody's guess !

Radio amateurs and professionals suffer from delusions of accuracy.

One rule of thumb is to always put nuts on the bottom. In this fashion, presumably if the nut were to vibrate loose and drop off at least the bolt would still be in place and this might save something from falling.

I recently compared an Old ARRL Antenna manual to a current handbook. The antenna theory was well thought out long ago and the laws of physics hasn't changed

Hams and others have developed a bunch of ideas to shorten or make antennas multiband. But there hasn't been a breakthrough in antennas in years. This has not kept up with radios and computer technology at all.

Maybe we already know everything or just do not have enough people working on the problem!

Richard,
I have read else where that there were concerns regarding nuclear
radiation hazards with respect to solid state components. I also seem
to remember seeing something about radiation resistant components.
Either way we all know that solid state radios have their own failings
.
I would imagine the thinking was that harm provided upon solid state
components
is instantaneous and final whereas human beings tho suffering from
radiation
had the ability to get in the defensive mode long before the onset of
a terrible
death. There is the thought that a submerged submarine could provide a
modicom
of safety where an antenna is not afforded equal protection.
I still have my draft card but if called I could send a letter that
clearly demonstrates my lack of reasonable communication.
Story.
When called for duty in the U.K. I was confident that I would be
refused because of perforated ear drums.
This was not so and by the time I got back to the office there was a
large
cartoon showing a skinny man (me)who was dressed down to nothing and a
nearby
physician with that 'y' shaped thing around his neck, was smoking a
cigarete,
blowing smoke into one of my ears and observing the high velocity
smoke being emitted from my other ear. I didn't see the funny side at
the time. My success was that the City of Nottingham was never invaded
during my service years which I atributed to be because every bone in

my body was seen to be an instrument of death by the enemy.

> in the equation. It might help on some bands but
> probably hurt on other bands.

With a bogie rolling back and forth on the wires, there is *literally only one variable* (as explored linearly by the 'back and forth' rope and pulleys).

The real question is: does the stub that varies oppositely to the line length preclude finding a match ? Worst case, if the stub length is being nasty and translating the far end open circuit into a dead sort a quarter lambda up the line in an annoying sort of way, then you simply 'turn the tables' by shorting out the far end (with a husky relay) and get an open circuit a quarter lambda upstream (ta da !).

The advantage to the proposed system is that you wouldn't have to worry about rolling up the unwanted line length (complicated mechanism) or finding a way to make it disappear from the circuit (many switches, relays or jumper plugs). It is also infintely variable - in one dimension.

The practical difficulty might be maintaining a good contact between the bogie and the wires. There is a half dozen ways to deal with that issue.

Art, with all respect, why must you depend upon and regard this group of *amateur* radio operators as the prevailing body that must pass judgement on your antenna for it to have any merit or value?

You claim a new invention, have a patent (I think you said) but evidently you are now just sitting around and writing complaints to the newsgroup because no one is jumping up and down with enthusiasm.

I guess I am most disturbed by your continued pleas for someone (an "authority") to explain to you and the world what you have and how it works. I may be wrong but it seems to me that you should be teaching *us* about your ideas and explaining to us how your antenna works and what is can do, etc.

I think it is more than unfair to the list for you to expect us to justify your concepts and authenticate your methods. That is *your* responsibility, not ours.

Why are you not disclosing this in the professional journals under peer-review? Why are you not pursuing the manufacture and sale of this antenna? Why is the approval of this particular group so important that its absence or at least deferral stands in your way of progressing in your own business?

I mean no disrespect but I just cannot equate your enthusiasm for your invention with your reluctance to do anything about it except complain to the members of this newsgroup about their attitudes and lack of support.

A major stumbling block, to be very frank, is that after having read all your postings, I still cannot begin to imagine what you are talking about, and I do have some background and education in the business. So, I am unable to comment one way or the other on what you are presenting as I simply cannot understand what you are trying to describe. I suspect many others share that position.

Finally, gaining the support of this group may work wonders for your self-confidence and morale, but as far as helping to further your professional image or serving as a lever for venture capital to manufacture these antennas, I am afraid that you are looking in the wrong direction.

Get some professional help to write a definitive analysis and description of your antenna. Get it informally peer-reviewed to catch the easy stuff. Then submit it to the appropriate professional journal(s) and let the scientific community do its thing. If validation is forthcoming, you are there. If not, at least you will have solid critiques to guide you in the sequel.

Then, come tell us what a wonderful antenna you have, how it works, and how much one will cost! <:}

All the best, Art. No one means you any ill will - we just can't follow what you are saying or why you are so dependent upon us.

Doc, most hams, savvy about antennas, know that a signal generator has
built-in circuitry that can be switched in to absorb the reflected energy.
That's why I fed the system with a signal generator instead of a ham
transmitter. I certainly wasn't playing games. I just assumed too much
which is a common failing of mine.

The problem here is not getting power into the antenna - that can be done.
Antenna driving-point impedance is of importance but is not the problem
with this proposal.

The problem is that the radiation from one leg will be largely cancelled by
the radiation from the other leg. Spread them out as far as possible and
see what happens . . .

> length preclude finding a match ?

Probably depends upon what one defines as a "match". I depend upon the current maximum point having a virtual impedance between 25 + j0 ohms and 100 + j0 ohms. If the stub changes the SWR on the 450 ohm ladder-line to less than 4.5:1 or greater than 18:1, then the current maximum virtual impedance will fall outside those values. However, it would be an interesting experiment.

A subset of that experiment might be a resonant 1/2WL dipole on 75m fed with 1/2WL of ladder-line. Then short out part of the line to achieve a match for the one wavelength dipole fed with 3/4WL of ladder-line on 40m.

Almost but not quite . . . Richard and I would differ on only one point: at which plane does the actual re-reflection take place - at the tuner output or the tuner input.

The reflected wave *does* pass through the tuner all the way to the input port where it meets the forward wave coming from the source. If the tuner is properly adjusted - and for the purists is lossless - then the phase of the voltage and current components of the reflected wave will be such that their combination with the incoming forward wave will result in total re-reflection of the reflected wave back through the tuner,etc. This behavior is verified by the zero reflected power condition in the transmission line from the source to the tuner, as Richard states. Note that the reflected wave must pass through the tuner in order for its transfer function to effect the required phase changes. For it to occur at the tuner output, the tuner itself would have to present an effective Zo of 50 ohms so as to terminate the coax to the source. This is neither feasible nor necessary.

This is the explanation given by Walter Maxwell in "Reflections" and confirmed by Warren Bruene in his January 1995 CQ article "Reflected Power Stays in the Coax." As much as those two gentlement have disagreed about conjugate matching, that is at least one point on which they agree according to their publications.

It is a common misconception that the conjugate-match impedance situation at the output terminals of the tuner - where the feedline to the antenna is connected - is responsible for re-directing the reflected wave. If you will think about it, however, the cancellation of reactances at that plane is precisely what is required for the reflected wave to pass unattenuated into the tuner and cause currents and voltages in its lumped circuit components. And for the forward wave to pass unattenuated to the antenna.
Richard says the same thing with better words, perhaps.

The tuner merely provides a convenient way for adjusting the length of the line such that the impedance at the tuner input has been made resistive at the usual value of 50 ohms and that the reactance present in the line input impedance has been cancelled. Remember that there is always a length of line that will present a purely real impedance at its input but that the value is seldom what is required. Similarly, the line length that provides the required real component is always accompanied by an undesired reactive component.

The tuner kills two birds with one or two twists of the knobs: extend the line length to provide the desired real component and present a conjugate of the reactive component. That is the tuner function in transforming the line input impedance to the real load required by the source. Its other

function, accomplished transparently in the course of accomplishing the impedance transformation, is to effect the proper phase alterations in the reflected wave voltage and current such that the waves combine at the match point plane - the tuner input - and produce in total re-reflection.

To summarize, the input plane of the tuner constitutes the "match point" where the incoming forward wave from the source and the phase-shifted and reactance-cancelled reflected wave meet, combine and join to emerge at the tuner output as the forward wave. It is in this manner that the forward power can exceed the amount of power delivered to the tuner/antenna system and utlimately delivered to the antenna (load).

2558. Re: G5RV in a V pattern? Possible?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-11 10:00:22 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D5635B6.2080009@eznec.com>
Source record: 137199

When two wires are fed in such a way that the fields cancel, the result isn't necessarily that the overall radiated field is less. Take for example an 8JK antenna. This consists of two parallel elements fed out of phase, and spaced much closer than a half wavelength (typically 1/8 to 1/4 wavelength). The fields from these two elements don't fully reinforce in any direction; they partially or fully cancel in all directions. Yet the antenna produces more gain than a single element.

If you put 100 watts into an antenna, 100 watts is radiated, less the power dissipated as heat. Pattern or field cancellation isn't a lossy process -- it's simply the superposition of waves in space. The 100 watts of power radiated is the power *after* fields are all added up and cancellation and reinforcement have taken place. You don't put 100 watts into an antenna and make it disappear by field cancellation. So an antenna whose fields cancel doesn't necessarily radiate any less power than one whose fields reinforce.

Here's what does happen. In a W8JK, the mutual coupling between the elements causes the element feedpoint resistance to be lower than for a single element. This results in higher current for a given power input, which in turn causes the fields to be greater. The result is that the overall radiated power is the same as it would be for a single element -- the extra field strength resulting from the heavier current just makes up for the loss of field strength due to field cancellation.

There is a practical limit to this technique, however. Heavier currents result in higher I^2*R loss in the elements. This can be reduced by increasing the conductor size, and can be made negligible for reasonable element spacings. But if spacing gets too close, the currents become high enough that significant loss occurs for any practical conductor size.

An inverted vee works the same way. One with a narrow angle radiates just as much power as one with wider spacing, less loss which occurs due to higher currents. For moderately narrow angles, the loss is usually insignificant. But with narrow angles, the feedpoint impedance is low, and it's difficult to match and feed without too much loss in the matching network or feedline. The tuning will also be narrow band. And if the wires are cut to be the proper length for a wider-angle inverted vee, a substantial amount of reactance will be present, making matching more difficult. So if a narrow-angle inverted vee works poorly, it's because not enough attention was taken to feeding and matching a low impedance antenna with low loss, not because of field cancellation. The problem truly is one of getting power to the antenna. Once there, nearly all of it will be radiated.

Why should any of the 'porn' stuff bother me? It
doesn't hold any special attraction for me, nor do I
particularly care what other people do with them. If
you have favorite 'porn' sites you wish to post, I would
suggest that you do so in an NG that caters to that. I
certainly don't think that this NG is the appropriate
place to do so.
In one of your posts you expressed a thought that you
should have been in 'marketing'. I think I agree with
you. You seem to have the ability to exaggerate, give
false impressions, and misconstrue facts that are a symptom
of the 'marketing' industry. For example, your generous
offer not to copyright uncopyrightable material. How do
I know the material is uncopyrightable? you said so your
self.

Yes. You'll also find that ground characteristics won't make much difference with this antenna. That's because horizontally polarized waves are reflected very well from ground of even fairly poor quality, except at high radiation angles.

> Is such a model a good approximation for the same yagi over sloped
> ground? (I would guess no, because I would speculate that the sloped
> ground would screw around with the ground reflection angles...plus what
> else?)

No, unless you also tilt the results. To see what would happen with a tilted ground (with constant tilt extending at least several wavelengths), tilt your Yagi the other way, run the analysis, then tilt the resulting elevation plot. But you'll find that tilting the Yagi has very little effect on the elevation pattern. This is because the basic elevation pattern of a Yagi is very broad -- you can confirm this by doing an elevation plot of the Yagi in free space. Tilting the ground will change the elevation pattern; tilting the Yagi won't change it significantly. A shame, isn't it?

To see the effects of complex ground contours, I recommend TA (Terrain Analysis) by Brian Beezley, K6STI. You can contact him at k6sti@n2.net.

That's what the spacers are for. The pre-ladder line
open wire feed lines used some type of spacers, usually
made from ceramic, plastic, wood, whatever. Since the
'wire' is bare copper (at least the last batch that I
saw was), making contact shouldn't be that big of a deal.
Use a reel large enough to accomodate the spacers used,
and incorporating the devices for making contact with the
wire in the feed line, doesn't seem like an impossible
project (again, I'm not the one actually making this thing).

Okay thanks. That more or less confirms what I've found "using" the real antenna. I was hoping to model my whole system of antenna's to get a general idea of how several wires in the yard, at all various angles, might be effecting the patterns.

But most of them are too low to have a "pattern" anyway. Still better than the proverbial light bulb. :)

Pure aluminium is pretty useless except as an electrical conductor. Have you ever tried climbing a pure aluminium ladder ? It's quite safe because you won't get beyond the first rung.

It's always alloyed for structural purposes. The physical and chemical properties of aluminium alloys (and there many sorts) are altogether different from the pure stuff except that they are all lightweight.

Hello Ron,

With a 1/4-wave centre-fed dipole on 160m a tuning-up problem is
guaranteed..

The only solution is to lengthen the dipole. Adding 20 feet to each end,
sideways, downwards or sloping, will make a considerable difference.

A 1-to-1 balun will be helpful on most bands. Important - keep the length
of coax between balun and tuner to an absolute minimum. Zero if possible.

If you are interested in numbers, to minimise floundering about in the dark,
download in a few seconds program DIPOLE3 from website below. No unzipping
inconvenience. Run immediately.

Enter details of your existing dipole + feedline + balun + coax to find
where the problem(s) lie. The L and C values of the L-match network you
should be using will be automatically displayed together with losses in the
various parts of the system and overall efficiency.

Then add 20 feet of wire to each end of the dipole to discover the
improvement obtainable. To see instantaneously what happens on all other
bands just change frequency. When L-match components have reasonable values
very likely you will be able to use your T-tuner. Trouble on a higher
frequency band can usually be remedied by changing ladderline line length by
a few feet.

Download program DIPOLE3.

Technically, it is not "total re-reflection", George. It is a combination of re-reflection and interference. Bill calls it cancellation. Walt calls it "a complimentary reflection that compensates and cancels". Thus, there are two phenomena involved in re-routing the reflected power back toward the load. I agree with you that the cancellation occurs at the input of the tuner.

Steve is right when he says: A total re-reflection requires a short, open, or pure reactance. None of those conditions exist at the input of the tuner.

If the reflection coefficient is 0.707, half the reflected power is re-reflected and half the reflected power is canceled in an interference pattern. That's why I have started using the term "re-routed" rather than "re-reflected". Re-reflection is only half the story.

"The reflected wave "does" pass through the tuner all the way to the input port where it meets the forward wave coming from the source."

Yes. I mis-spoke when I said the wave bounced off the tuner output or transmitter output (absent the external tuner) or something to that effect. My intended point was the flat line between transmitter and tuner proved absence of reflections on that line.

When I cut corners on verbage, I often make mistakes. But, more often I make mistakes as an expression of the wrong idea. In this case, I don`t remember what I knew and when I learned it.

Best regards, Richard Harrison, KB5WZI

I just bought some open-wire feed line but it uses insulated
wire. The spacers appear to be made out of plastic irrigation
tubing.

>Can anyone speak about the accuracy of an Eznec(v3.0.42) model of an antenna over "real" ground?<

A couple weeks ago, I used EZNEC to model a parallel reflector at 60-feet for my 75 dipole to make up a 2-element wide-spaced yagi (over real ground). I then installed the reflector exactly as modeled. There's no way I can confirm the behaviour of the pattern other than by general impression, but EZNEC predicted the feedpoint impedance and SWR (both before and after my installation) with uncanny accuracy--giving me at least some degree of confidence that the model might be predictive of the antenna's performance other ways.

Bill said:
> > If you agree that part of component #5 is transmitted on toward the
> > load, then you should have no disagreement that part of component #6
> > is transmitted on toward the source.
>
> It tries to be transmitted on toward the source but doesn't make it
> because of destructive interference which you call cancellation.

Here's an expanded version of what I posted yesterday:

Reflection coefficients are computed using the usual equations
rhoV for voltage waves
rhoI for current waves

Transmission coefficients (from Kraus)
tauV for voltage waves, given by 1 + rhoV
tauI for current waves, given by 1 + rhoI

The notation "mag/phase" represents a complex value.
Multiplying by a negative number inverts the phase (0 to 180 or 180 to
0)

Component #1: assign a phase of zero to component #1.
V+ on the coax is 70.7/0 v, I+ on the coax is 1.414/0 a
(I won't repeat the impedance and power relationships.)

Component #2: at the coax-twinlead junction, rhoV is 0.5, rhoI is -0.5
V- on the coax is 35.36/0 v, I- on the coax is 0.707/180 a
Note the phase inversion on the current wave.

Component #3: at the coax-twinlead junction, tauV is 1.5, tauI is 0.5
V+ on the twinlead is 106.7/0 v, I+ on the twinlead is 0.707/0 a

Component #5: ("supersum" of Component #3 and Component #4)
the waves add in phase resulting in:
V+ on the twinlead is 141.4/0 v, I+ on the twinlead is 0.943/0 a

Component #6: at the right-hand twinlead-coax junction,
rhoV is -0.5, rhoI is 0.5
V- is 70.7/180 v, I- on the twinlead is 0.472/0 a
Note the phase inversion on the voltage wave.

Component #7: at the (left-hand) coax-twinlead junction,
tauV is 0.5, tauI is 1.5
V- on the coax is 35.36/180 v, I+ on the coax is 0.707/0 a

At this time instant, component 7 is the result of waves traveling
one-half
wavelength toward the load and then traveling another one-half
wavelength toward
the source. So the time for one full cycle has passed. Therefore, the
V and
I waves *from the source* that are currently incident on the left-hand
junction
have the same phase as those forcomponent #1, 0 degrees. These waves
are
partially reflected at the left-hand junction resulting in a component
that is
identical to component #2. For these waves,
V- on the coax is 35.36/0 v, I- on the coax is 0.707/180 a

Let's summarize and identify each one explicitly
component 7 (the result of wave components that have traveled up and
back along
the full length of the half-wave line) is waves that are traveling
toward the
source from the left-hand junction

component 2 (the result of wave components reflected from the
left-hand
junction) is waves that are traveling toward the source from the
left-hand
junction

V7- is 35.36/180 v, I7- is 0.707/0 a
V2- is 35.36/0 v, I2- is 0.707/180 a

V7- and V2- exactly cancel, no voltage waves on the coax
I7- and I2- exactly cancel, no current waves on the coax

Note that the cancellation doesn't occur just at one point, but at
every point along the coax from the left-hand junction back to the
source. This is because the waves are travelling in the same
direction.

> > Now in general each reflection or transmission coefficient is a
> > complex quantity and has a phase associated with it. For the simple

> year or so ago. Steve is not including those cancelled voltages in his voltage
> equation and those cancelled voltages are what furnish the energy foundation

> for the forward wave on the 150 ohm line.

But if the voltages and the currents are cancelled at every point on
the coax, they cannot possibly contribute any energy anywhere. They
are annihilated and so is their energy. And the words "furnish the
energy foundation for the forward wave" don't even make sense.

> As you say, Component #2 and Component #8 cancel, i.e. engage in destructive
> interference. The constructive interference power heads back toward the load.

I didn't say anything like what appears in the second sentence. And if
there is destructive interference, there can't be constructive
interference (the addition of components) there or anywhere else. You
can't have it both ways.

> Thanks Bill, it seems that we are essentially in agreement. The voltage equation
> balances and the power equation balances.

Well, we're not essentially in agreement, but it did give me a chance
to try partial reflection/partial transmission for a new type of
problem. And it works. 73,
Bill N3WK

Whoops Bill, you stepped in it there. Energy in a transmission line CANNOT be annihilated. That would certainly violate the conservation of energy principle. Waves can be annihilated but the energy in those waves has to go somewhere. Energy cannot disappear from the universe. The energy in the cancellation effect joins the forward energy on the twinlead. Energy is like a balloon. Make it smaller in one place and it gets larger in another place.

> > As you say, Component #2 and Component #8 cancel, i.e. engage in destructive
> > interference. The constructive interference power heads back toward the load.
>
> I didn't say anything like what appears in the second sentence. And if

> interference (the addition of components) there or anywhere else. You
> can't have it both ways.

Antennas have it both ways, Bill. We get destructive interference in one location so we can obtain constructive interference in another location thus obtaining gain over an isotropic antenna. The conservation of energy principle says that for every destructive interference there exists an equal constructive interference. The 50 joules per second involved in the destructive interference on the coax joins the forward wave on the twinlead as constructive interference and contributes to the 133.33 joules per second in the forward wave. To summarize:

75 joules/sec is not reflected at the coax/twinlead junction and joins the forward wave joules/sec on the twinlead.

8.33 joules/sec of the reflected energy is re-reflected back toward the load and joins the forward wave joules/sec on the twinlead.

50 joules/sec is involved in destructive interference at the coax/twinlead junction. Since there is no reflected energy on the coax, the only other thing that can happen is that this 50 joules/sec joins the forward wave joules/sec on the twinlead.

Thus: 75 joules/sec + 8.33 joules/sec + 50 joules/sec = 133.33 joules/sec

Why do so many RF engineers insist on violating the conservation of energy principle when it is completely unnecessary?

A vertical is one way to go. You can also do well with a stealthy dipole. A dipole for 20 meters is only 33' long, total. And that will talk all over the world. Dipoles for the higher bands are even shorter -- a 10 meter dipole is only 16'. So it may be tricky to get on 40, 80 or 160 from your lot, but the higher bands are well within possibility, especially with the tree you have to hold up one leg of a wire antenna.

Other than that complicated bit around 'black holes' (more of a complication than an exception) and the other complicated bit about "E=mc&#65533;", CAM is perfectly correct w.r.t. conservation of energy. Transmission lines need to adhere to this rule; loss is okay - annihilation of energy isn't.

Mark -

You should look at the Cubex Quad product line (Mantis Series)for some ideas.
http://www.cubex.com/
The Mantic series, 2 elements runs around $1,400

W9DX does run a 40 meter Quad antenna .. its big (photos on the Qubex web site)
http://www.cubex.com/pho.htm

http://www.antennex.com/Sshack/quads/quad2.htm

That complication around black holes is why I added "in a transmission line". :-)

>

Thats not what I said at all. 100 V forward + 100 V forward (in-phase)
results in 200 V forward not 400 V forward. So, in a 50 ohm line you would
have 200 V at 4 A. The resulting forward power would be 800 W.

> In your example, you are adding 106.07v at 0.707a (75w) to 35.35v at
> 0.236a (8.33w) to get 141.4v at 0.943a (133.33w). Why is that not
> the same thing as above?

I think you are confusing concepts, examples and situations so lets consider
it from this simple perspective.

Lets assume that we have a constant 100 V source connected to a 50 ohm load.
The resulting current in the 50 ohm load is 2 amps. The power dissipated in
the 50 ohm load is 200 W. In this situation we could say that this is a
"200 Watt power source". In reality, it is only a constant 100 V source.
Presuming that it is a "200 Watt power source" is only a result of the fact
that it is a 100 V source connected, by itself, to a 50 ohm load. The law
of conservation of energy is maintained because the source delivers 200 W
and the load dissipates 200 W.

Now lets say we have a second constant 100 V source. When we disconnect the
first 100 V source and connect this second 100 V source to the 50 ohm load,
we have the same situation as above. The second source delivers 200 W of
power and the load dissipates 200 W of power. Again, we could call this
second source a "200 Watt source". But again, this is only a result of the
load it is connected to.

Now lets connect both of these constant 100 V sources in series to the load
at the same time. Are we now connecting two "200 W sources" and would we
expect the total power dissipated in the 50 ohm load to be 400 W (200W +
200W)? No, not at all. The fact that 200 W of power is delivered to the

load when each source is connected individually to the load is irrelevant. All that matters now is what happens when these two constant 100 V sources are connected to the 50 ohm load at the same time.

When both of these sources are connected to the 50 ohm load at the same time, the total voltage in the load becomes 200 V (100 V + 100V) and the total current becomes 4 A. The total power dissipated in the load becomes 800 W, not 400 W. We could now think of this situation as an 800 W source delivering 800 W of power to a 50 ohm load. The law of conservation of energy is maintained because the "new source" delivers 800 W of power and the 50 ohm load dissipates 800 W of power.

Using direct power addition to determine the total power delivery when adding multiple voltage sources to the same load does not work. You cannot think of this situation as adding two 200 W power sources together to get 400 W. The law of conservation of energy is not violated because total power is conserved - the source delivers the same amount of power that the load dissipates.

In the transmission line situation, consider the following forward voltage additions and the resulting total forward power in each case. Lets assume that we have two 100 V forward voltages in a 50 ohm line that combine to result in a total forward voltage. Individually, each of these forward voltages is equivalent to 200 W of forward power, regardless of their individual phase. When combined however, the resulting forward power can range from 0 W to 800 W as a function of how the individual voltages add as vectors. At no time is the law of conservation of energy violated.
Examples

100 V @ 0 degs + 100 V @ 180 degs = 0 V and 0 W forward

100 V @ 0 degs + 100 V @ 90 degs = 141.42 V @ 45 degs and 400 W forward

100 V @ 0 degs + 100 V @ 0 degs = 200 V @ 0 degs and 800 W forward

The specific example conditions that result in these situations are irrelevant. These relationships always hold. We do not have to consider the law of conservation of energy for these relationships to hold. Validating the law of conservation of energy in anyone of these situations is done by examining what happens in the entire system.

Hi Art--

>Fractenna was blasted because his was a 'new' idea yet all forgot what possible advantages it presented.<

In my view, fractenna was blasted not for "his new idea", but for his bombastic misuse of the antenna newsgroup. The fractal debate continues, albeit less dramatically these days, through the IEEE were a small community of interested researchers explore both the "possible advantages" and the inherent disadvantages of fractal radiators. Fortunately, when you play at their house, you are expected to behave yourself and keep your fingers out of your nose.

> Best regards, Richard Harrison, KB5WZI

Thank you, thank you, thank you, for getting back to basics.
I will say again, I have no money motivation in all this. I do not
believe I have broken any law of physics and I have not "invented"
anything new. It was there all the time but people have ignored it
presumably because it has been presented poorly in a too technical
way, or nobody has connected the two articles that I presented as
links with their accompanying explanations in the relevant antenna
books.

So let me cut it down to as few lines as possible
to make it easier for all to refute.

1. Accepted law. F1 +/- F2 =F3

2. Accepted fact.
A resonant loop ca be made resonate at other
frequencies by the addition of a capacitor

3. When two resonant circuits are placed close
together which is called coupling it can
change the frequency at the point of coupling.

#4. If you drive a portion of one of these two
resonant circuits with a particular frequency
it will radiate a signeal of the same frequency.

5 If the other resonant structure which is coupled
receives energy it will either null radiation
from that portion or radiate at a frequency
in accordance to law #1 shown above.

.

6. The resulting current pattern will comprise
first of a pattern expected for the injected
signal but ONLY upto the point of actual oupling.

7 The coupled portion will will have zero to little
current flowe at a different frequency and thus
will not radiate in a similar way as the uncoupled
co-joined elements

8 The final current curve for the whole structure
will comprise of TWO POINTS OF CURRENT MAXIMA
which provides for COLLINEAR GAINS collinear
gains over a dipole of it same over all
electrical length.

What laws of physics have I broken ?

Best regards to you Richard.
The question that I have raised is pointed at the
whole group and I thank you personaly for keeping
an open mind ispite of the agravations that I may
have unintentially imposed . If there is something
even tho small is proved in the above then ham radio
will benefit.

2586. Re: G5RV in a V pattern? Possible?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-11 16:01:01 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <3D568A3B.3F18C892@att.net>
Source record: 137126

Roy, unless I totally misunderstood the original posting, the antenna in question is a G5RV mounted in a horizontal V configuration, not the usual vertical-plane inverted V, with the ends of the antenna some 20 ft apart.

I was attempting to point out that having the ends of the legs too close together would result in poorer performance relative to that of a dipole than with them further apart, as in 180 degrees.

No argument that all the power reaching the antenna is radiated. But what if the two ends were placed only, say, 4 " apart and the antenna were a 1/2-wave dipole? Would the antenna not then constiute a 1/4-wave open-ended transmission line with equal and opposite currents in each leg? And would not all radiation be essentially cancelled?

What happens to the power applied in this case? The line termination is a direct short which would produce total reflection and no power would be accepted by the antenna to be radiated. Hence, no conflict with Conservation of Energy.

As the ends of the legs are moved apart, a real component in the driving point impedance is developed and power begins to be accepted and radiated - all of it, as you point out - in some field form or other.

As the spacing increases until it reaches 180 deg, the driving-point impedance becomes whatever it is for that piece of wire at that location. And the real part will accept power and it will be radiated in the manner of the dipole it has become.

Hello

I want to set up a random wire antenna going from the wall of my house to some kind of mast, roughly 20 foot tall. Any ideas on a cheap way of constructing a mast? I could cope with pouring some concrete in a hole a setting a length of plastic tubing in it as a base, but what would be a good cheap material to act as the mast, that would take the weight of the wire?

I have measured mine which happens to be on the
ground at the moment. The diameter seems to be between 10 and 11 inches.
It is hard to measure because of the center post.

You shouldn't have to be all the way towards the radiator. Mine "usually" tune about in the middle of the coil. If you don't get a good match no matter where you tap the coil, you may need the tweak the cap value or radiator length. I show the "normal" length for the C/C version as 7 inches, or 18 cm long. I'd probably set the radiator height as about 111.75 inches or so to tune 50.25 mhz. I've built one

of these antennas for 6m and had no problems tuning it. It acted the same as my 10m versions. If you are ending up tuned to 52-54 mhz, I would think your radiator is a bit short. The loop/cap is just an impedance matching device. If your antenna is short or long, the matching device is not going to be able to "pull" it into tune too much. You will have to adjust the radiator. Don't give up. It will work with a flat 1:1 swr. I just looked at mine out in the backyard. Now, mine is tuned for about the middle upper part of the band, for FM use. "about 52-52.5 mhz" My radiator is 104.5 inches. My loop is made from 3/8 inch copper tube, and is appx 6 inches dia. The tap is about 6 inches from the base, or about 1/3 the way from the base to the radiator. My cap is exactly 8 inches long of rg-58. As I remember , it had a good match. But I haven't used it in quite a while. I built a 3 el yagi since then.

> I've been using RG-8/U coax to feed it, but I'm beginning to think it's
> perhaps decomposed somewhere along the run. I guess it's time to drag out
> the Cantenna. It's a shame when you can't trust new coax to really be
> "new".

I doubt it's the coax. Bad coax gives you easier matches than good coax. Really bad coax will make anything look good. You can take real bad coax, stick a pin in the far end, and still see a decent SWR.

> Anyhow, thanks for the feedback. I wanted to make sure I was close to the
> right ring size before I tossed the feedline.

I think your radiator needs to be longer. About 111.75 inches or so I think would be right for the bottom end of the band. When working properly, the tap for the loop will be about in the middle of the range. The cap value is not critical, but can be trimmed for best match once you get everything in the right ballpark. Usually, you don't need to as the loop tap will give you enough leeway. MK

The 400 volts was a typo, Steve. I meant 200 volts. And you CANNOT get
800 watts out of two 200 watt waves. Please show me how to hook up two
RF generators, each putting out 100 volts at 2 amps to obtain 200 volts
at 4 amps.

Not if the power output of each generator is limited to 200 watts!!!!!
You have the generators delivering twice as much power. That's not true
of the waves you are adding in the transmission line. Each of those waves
have a FIXED power associated with them. A forward wave of 106.066 volts
and 0.707 amps in a 150 ohm feedline has a power of 75 watts associated
with it, no more and no less. You cannot magically obtain more energy out
of that wave by adding it to another wave. A wave of 75 joules/sec added
to a wave of 8.33 joules/sec cannot result in 133.33 joules/sec. "75 joules
plus 8.33 joules equals 133.33 joules" certainly violates the conservation
of energy principle. Please see my exchange with Bill Klocko.

Please answer my question, Steve. When the load in the earlier example is
switched from 150 ohms to 50 ohms, the power delivered to the load increases
by 25 watts and 25 watts is no longer dissipated in the signal generator.
How does the 25 watts that was previously dissipated in the signal generator
make it to the 50 ohm load without a voltage and current component?

Art, KB9MZ wrote:
"#1. Accepted law. F1 +/- F2 = F3.

"5. If the other resonant structure which is coupled receives energy it will either null radiation from that portion or radiate in accordance to law #1 shown above."

Art`s #1 seems to be the heterodyne story of sum and difference mixing products. This requires a non-linear circuit (a loop doesn`t qualify), maybe a mixer such as a diode.

Art`s #5 seems to correctly indicate a coupled radiation structure producing destructive interference (in some direction, which means it also produces constructive interference in another direction), or it can produce sum and difference frequencies.

Coupled radiators produce a directional pattern. They usually are linear and so they do not produce mixing. Combined radiation from coupled radiators is limited to the exciting frequency(s).
The frequencies mentioned in bandwidth specifications are limits at which the antenna signal level is reduced to an arbitrary level, often 3 db below the best level, or half the maximum power in the best direction.

This means that when the antenna is excited at the limit frequency instead of it`s maximum gain frequency, its response will be down by the arbitrary amount. This has nothing to do with the antenna generating extra frequencies when excited.

Best regards, Richard Harrison, KB5WZI

Source record: 137134

Thanks to Steve and Bill, I now have a relatively simple example that illustrates what I have been saying ever since an argument with Jon Bloom a few years ago over his QEX article, "Where Does the Power Go?"

The following example is driven by a signal generator which contains circuitry that causes all reflected energy to be dissipated. Except for the dissipation in the signal generator and the load, the system is lossless and there are no common mode components.

```
100w Source---50 ohm feedline---+---1/2WL 150 ohm feedline---+
| |
| o---/\/\/\/\/\/\---+
| switch / Load ^ 150 ohms tapped
+--------shield-------------------o | at 50 ohms
|
o----------+
```

With the switch in the 150 ohm load position, there is 100w of forward power on the 50 ohm feedline. There is 25w of reflected power on the 50 ohm feedline that gets dissipated in the signal generator. The forward power on the 150 ohm feedline is 75w and 75w reaches the 150 ohm load resistor because there are no reflections from the 150 ohm load.

Now the switch is thrown to the 50 ohm load position. The forward power on the 50 ohm feedline remains at 100w but now there is no reflected power on the 50 ohm feedline so there is no dissipation of reflected power in the source. We now have 100w reaching the 50 ohm load resistor. The power dissipated in the source has decreased from 25w to zero watts. The power in the load has increased from 75w to 100w.

The question is: How does the 25 joules/sec get from the source to the load without contributing to a component of forward voltage and current on the 150 ohm feedline?

The answer is that it does contribute to forward voltage and current on the 150 ohm feedline and needs to be taken into account in the equations.

You're placing very specific constraints on the example. They're constant
100 V sources. Why, to discuss basic concepts, do you need to limit their
output current to 2 A? It seems that you're trying to limit the example
conditions to satisfy your preconceived conclusion.

> > When both of these sources are connected to the 50 ohm load at the same

>
> Not if the power output of each generator is limited to 200 watts!!!!!

You're trying to limit the discussion again. Why do we need to limit the
source to 200 watts maximum output power?

> You have the generators delivering twice as much power. That's not true
> of the waves you are adding in the transmission line. Each of those waves
> have a FIXED power associated with them.

Only when they are considered as being independent waves existing alone in
the transmission line. We are discussing what happens when multiple
"independent waves" combine together in the same transmission line. The
"fixed power" of the individual waves is no longer a valid concept. There
are simply multiple forward voltages and currents combining to become the
steady state total forward V and I. The power in the total wave is a result
of the total V and I. Everything else that happens in the system ensures
that the law of conservation of energy is satisfied.

The relationships associated with adding multiple forward voltages and currents remain valid at all times. 100 V + 100 V (in phase) will always equal 200 V. 200 V forward in a 50 ohm line is always equivalent to 800 W forward. From your perspective, you want to limit either the resultant current or voltage so as to maintian a very specific power relationship.

> Please answer my question, Steve. When the load in the earlier example is

> --

I'm not sure what earlier example you are talking about. In any event, what you are talking about does not change the relationships associated with adding forward voltages and currents.

Start with a simple example where you have a fixed voltage source with a fixed internal impedance and we can discuss whatever steady state conditions you want.

That is a good sign actually. If you didn't pick up noise, then I'd be
worried.
>
> So, my guess is that my random wire is probably a miserable match for these
> marine freq's.

It doesn't really matter if it is or not. The s/n ratio will likely be
unchanged if you added matching. All you do is pump up the S meter. If
you listen to the radio blindfolded, you will likely notice no real
difference.

>
> Also, there is a strong possibility that a major part of my problem is that

In your case you are receiving local "ground wave" signals. You will
need a vertical to do any good. Actually, I'm kind of surprised they
would be very active on those frequencies. Seems to me they would
favor the 162 mhz marine band for local stuff...
>
> I'm really new at this, so please don't hesitate to make the suggestions,
> and your thoughts on this, as detailed as

> you can-really appreciate the help.

For low band use, as a general rule, if you hear a good increase in noise when hooking up your antenna, the antenna is good enough for receiving purposes. "Not counting any prefered pattern" Actually, I consider this true even up to 30 mhz for general use. If you hear noise increase, but not the station, either the propagation is not willing, or the pattern of the antenna is nulling the signal out, or you have a polarization problem. Cross polarization can cost you 20 db in some cases. You might consider a homebrew small receiving loop. With that you can null out noise, etc. Should respond to vertically polarized signals ok. I have one of these I use for MW. It's a 16 inch circle with 12 turns, not counting the 2 turn coupling loop. With it's present variable cap, it tunes 500-2000 kc. A good antenna for your thing would be a outdoor inv L or vertical, but you have ruled that out.. MK

Cecil,

I musta been asleep in basic circuits class that day they discussed sources that can simultaneously force a specific voltage AND a specific current into any load. Last I heard it was the impedance of the load that determines the V-I relationship in the load, not some "wish" or "demand" from the source.

You have set up an impossible situation. Steve is correct.

I will assume identical voltage sources below, but the same argument holds for current sources or "real" sources.

Case one: The sources are combined in parallel, with the voltages in phase.

The resulting voltage into the 50 ohm load is still 100 volts, and the load current is still 2A. Load power is still 200W. What happens to the other 200W? You can choose from an infinite number of possibilities, but one answer is that the output current from each source drops to 1A, with the corresponding output power of 100W from each source.

Case two: The sources are combined in series, with the voltages in phase.

The resulting voltage into the 50 ohm load is now 200 volts, and the load current is now 4A. Load power is now 800W. Where does the "extra" 400W come from? Again, there is an infinite number of possibilities, but one answer is that the output current from each source rises to 4A, with the corresponding output power of 400W from each source.

You cannot arbitrarily force the conditions you propose. Something has to give, and either the output voltage, the output current, or both must change when you combine sources. If the sources cannot accommodate the new requirements then something will burn up or the proposed load conditions simply cannot be met.

The only thing that would make your scheme hang together is that somehow the load impedance changes to 100 ohms when the sources are combined in series. How does the load change happen?

I am familiar with Thevenin equivalent circuits and Norton equivalent circuits. It appears there is now something new to learn, the CAM equivalent circuit.

To add insult to injury, this sort of manipulation of the V-I characteristics forced onto the load, regardless of the load impedance, is just the sort of thing that makes the E-H antenna "work".

Hello Dear OM!

Carsten (DF2DD) and Andre (DL4QB.that's me J) are enthusiastic user

of Magnetic Loop Antennas. I searched for information about Magnetic Loops

since a while and I found some very interesting stuff at Carstens Homepage.

There is nice a board with less but very helpful traffic. It was very
helpful

to collect the needed information as well. In the meanwhile, we improved the

Board System and we would like to spent an own Domain very soon J

We thought also about an English part within the Board System. This is now

done and can be used! It would be very nice to get some nice information,

hints and experiences of other Magnetic Loop users.

If you can suggest someone this board, we would be happy as well J!

There are already some docs in German available.if you like to understand
it,

Please ask me and I will translate it for you.

> The power dissipated in the source has decreased from 25w to zero watts.
> The power in the load has increased from 75w to 100w.
>

Your power relationships, as described, are seriously flawed.

First, the *total* power dissipation in the system does not have to be the same in each example - this is not a requirement of the law of conservation of energy.

Second, the *total* power dissipation in the system does not have to be 100 W.

Third, the power dissipation in the source cannot go to zero watts with the 50 ohm load. If it did, there would be no current flow in the source's internal dissipating resistance (the R that "dissipates" the 25 W of

reflected power). So as not to violate kirchoffs and ohms laws, 0 A in the source R would require that the current in the effective load seen at the source output also be zero, thus requiring that no power be delivered to the load.

Fourth, the 25 W of reflected power does not get dissipated in the source quite the way you think.

A more correct way to present this example would be to use a fixed voltage source that constantly drives a 50 ohm line with 100 W of forward power. Your circuit diagram would look as follows:

141.421 V --- 50 ohm Zs -- + -- 50 ohm line -- + Load

Lets first assume that the load is 150 ohms.

In the initial state, the forward source voltage divides between the 50 ohm source impedance (Zs) and the 50 ohm line. 70.711 V forward is developed across Zs - the *initial* power dissipation in Zs is 100 W. 70.711 V forward is developed in the 50 ohm line. 100 W of forward power travels towards the load.

70.711 V forward arrives at the load. It sees a reflection coefficient of 0.5. A reflected voltage of 35.355 V is developed at the 150 ohm load. The total voltage developed at the load is 106.066 V. 75 Watts power is delivered to the load.

The 35.355 V reflected arrives at the source and sees a 50 ohm load - Zs. The 35.355 V is delivered across Zs. It is traveling in the opposite direction as the 70.711 V forward in Zs such that the total steady state voltage across Zs is 35.355 (70.711 - 35.355). The *total* power dissipation in Zs is 25 Watts. Note how the total 25 W is developed - from the combination of a forward and rearward traveling voltage and current. Note as well that the total power dissipation in the system is 100 W - 25 W in the source and 75 W in the load.

Now, lets change the load to 50 ohms from 150 ohms. In this case, the initial state is the same: 70.711 V forward is developed across Zs - the initial power dissipation in Zs is 100 W. 70.711 V forward is developed in the 50 ohm line. 100 W of forward power travels towards the load.

70.711 V forward arrives at the load. It sees a reflection coefficient of 0. No reflected voltage is developed at the load. The total voltage developed at the load is 70.711 V. 100 Watts power is delivered to the load.

Now, at the source, there is no arriving reflected voltage and the steady state voltage remains 70.711 V at Zs. The power dissipation in the source is now 100 W *not* 0 W. The total power dissipation in the system is now 200 W. 100 W in the source and 100 W in the load.

In order to analyze the power relationships in a transmission line system you must consider what is happening with the traveling voltage and current. Looking at only steady state power levels does not provide insight into the

complexity of the problem.

Nope, I'm limiting the example conditions to satisfy typical ham conditions.
A typical ham is running 70.7v at 1.414a into a 50 ohm Z0-match. There is
no additional current or power available!!!! If there is no additional voltage
available and no additional current available, how do you get additional power?

> You're trying to limit the discussion again. Why do we need to limit the
> source to 200 watts maximum output power?

Because the typical ham's transceiver is limited to 100 watts!!!! "Blood
out of a Turnip" comes to mind. So does the principle of conservation of
energy. Would you answer a question truthfully, Steve? Please select from
the following:

I, Steve,

a. have not taken the time to understand what Cecil is talking about.
b. have realized my mistake and am attempting to obfuscate the issue.
c. other (please explain)_____

Please help me to understand what you are missing about my argument.

> Only when they are considered as being independent waves existing alone in
> the transmission line.

See my exchange with Bill Klocko. He had no problem with breaking everything
down into independent components. He was forced to arrive at the same conclusion
as you did a year ago - that energy can be annihilated which is, of course,
false. Remember your phantom wave theory?

> We are discussing what happens when multiple
> "independent waves" combine together in the same transmission line. The
> "fixed power" of the individual waves is no longer a valid concept.

The fixed energy is certainly a valid concept!!! Waves in a transmission
line are forced to obey the boundary conditions. If a wave is 106.066 volts
at 0.707 amps in a 150 ohm transmission line, there is no way to get more
power out of that wave than 106.066v * 0.707a = 75 joules/sec except maybe
by supernatural forces or magic.

> There
> are simply multiple forward voltages and currents combining to become the
> steady state total forward V and I. The power in the total wave is a result
> of the total V and I. Everything else that happens in the system ensures
> that the law of conservation of energy is satisfied.

And we are discussing *exactly* what happens. Why are you trying to avoid
that discussion? Overtime I have pinned down an RF engineer on this subject,
he responds with, "That's not important." What are all these RF gurus trying
to hide/avoid. Is it possible that they have been spreading Old Wives' Tales
for so many years that they have forgotten what the facts are? - or maybe
they never knew the facts and we are, as we speak, revolutionizing reflection
theory?

> The relationships associated with adding multiple forward voltages and
> currents remain valid at all times. 100 V + 100 V (in phase) will always
> equal 200 V. 200 V forward in a 50 ohm line is always equivalent to 800 W
> forward. From your perspective, you want to limit either the resultant
> current or voltage so as to maintian a very specific power relationship.

No, no, no. I want to limit the energy to the total energy in the system.
The voltages and currents fall out from the total energy available. You
are simply ignoring the source of energy contained in the destructive
interference process. We had this discussion a year ago. Energy CANNOT
disappear from a point close to the source and magically re-appear close
to the load. Any energy transferred from the source to the load MUST be
contained in the forward energy wave. You are completely ignoring the
energy involved in the destructive/constructive interference process.

> I'm not sure what earlier example you are talking about. In any event, what
> you are talking about does not change the relationships associated with
> adding forward voltages and currents.

Translation: I refuse to answer because my answer would violate the
conservation of energy principle and thus prove that I am wrong.

> Start with a simple example where you have a fixed voltage source with a
> fixed internal impedance and we can discuss whatever steady state conditions
> you want.

Please see my latest example. It is a signal generator delivering a fixed
100 watts into a fixed 50 ohm feedline with no reflections. The load is
switched from 150 ohms to 50 ohms. The 25 watts that was dissipated in
the signal generator during the 150 ohm load is then re-routed to the
50 ohm load. How does that 25 joules/sec make it from the source (when the
load is 150 ohms) to the 50 ohm load (after switching) without becoming part
of the voltage/current contained in the forward wave?

Hello. I'm running a mobile 2M radio at home from a power supply. Any comments on what would be the best homebrew antenna to build for this that is not a yagi, I need an omni-directional one.

Any help or comments appreciated.

Scott

Gene Fuller wrote:
> I musta been asleep in basic circuits class that day they discussed
> sources that can simultaneously force a specific voltage AND a specific
> current into any load.

Sorry to disappoint you Gene, but a 100w ham transceiver working into
a 50 ohm Z0-match at the input of an antenna tuner *IS* forcing a specific
voltage AND a specific current into the antenna tuner. In particular, it
is forcing 70.7 volts at 1.414 amps in phase. The power output of the
transceiver is fixed and there are no reflections. These conditions exist
no matter what the antenna impedance or SWR. The energy into the system
(antenna tuner) *IS FIXED* at 70.7 volts * 1.414 amps = 100 watts.

> You have set up an impossible situation. Steve is correct.

The impossible situation is based on Steve's logic. If it is impossible,
Steve is wrong. It was a Primrose Path argument.

Everything you said after the above is irrelevant. We are dealing with a 100
watt ham transceiver delivering 100 watts into 50 ohms (antenna tuner) with
no reflections at the input of the tuner. If you are trying to divert the
issue, it won't work. If you simply don't understand, please pay attention.

Hello Julian,
I have had 30 ft of Radio Shack "heavy duty steel TV mast" on the roof
in a Radio Shack tripod mount for over 6 years with no issues at all.
It comes in 10 ft lengths and is about a "buck a foot" as I recall.
Maybe more now..since it has been over 6 years ago....

My only other comment is that I have seen some posts from Hams that
used 10 ft lengths of what they called chain link "fence railing"
because it was cheap and later regretted it because it bent and/or
sheared.

I know some Hams detest the words "Radio Shack" and condemn anyone
that uses them..however my RS mast sections and really every other RS
item I have ever owned has worked fine and continues to do so.

I do have links on my web site for Radio Shack manuals for all their
products, Ham Radio and otherwise...
1. http://www.ab7sl.com/index.html?row1col2=links.html

Hope this helps....good luck

You're absolutely wrong there, Steve. The signal generator is putting out a constant 100 watts into 50 ohms and dissipating all the reflected power it sees in a 50 ohm resistor. Aren't you familiar with signal generators? In this particular example, the total power dissipation in the system *MUST* be 100 watts. Sorry about that but that is why I chose this particular configuration.

> Second, the *total* power dissipation in the system does not have to be 100
> W.

Yes it does, Steve!!!! The signal generator is delivering 70.7 volts at 1.414 amps (100 watts) into 50 ohms. There is no other source. All the reflected power seen by the source is dissipated by circuitry in the source. I realize that circulators are not perfect, but for the sake of a conceptual argument, let's consider this particular circulator to be perfect and all the reflected power seen by the source is dissipated in a 50 ohm resistor..

> Third, the power dissipation in the source cannot go to zero watts with the
> 50 ohm load.

The power dissipation in the *source's reflected power circuitry* goes to zero watts. Absolutely nothing has been said about the source's internal impedance which is irrelevant since the source sees nothing except a 50 ohm load. This is where you tripped me up a year ago. This time, the problem doesn't exist.

> Fourth, the 25 W of reflected power does not get dissipated in the source
> quite the way you think.

Of course it does, Steve. It has a perfect circulator built in to route the reflected power to a 25 ohm resistor. Everything you had to say after this is invalid because you do not understand the configuration. Please try again.

'F' is about twice as effective as 77 material but that doesn't seem
to be your problem. I feared that you snapped a few Radio Shack cores
on the wires expecting magical results. Sorry.

I think I understand Steve's and Bill's argument now. Energy is turning into matter at the destructive interference point, running along the ground under the transmission line to the load, and then converting itself into energy once again at the load. Wow! And to think this was happening even before the Manhattan Project.

A J-pole made from 300 ohm twin lead is the first thing that comes to mind.
Another is a ground plane made from an SO-239 coax connector and 4-19" pieces
of some sort of wire with lugs on the ends for the ground plane. One 19" piece
of #12 copper wire soldered to the center pin of the SO-239 for the vertical
radiator. Trim the vertical wire and/or bend the ground plane downward for
best SWR.

Hiding the antenna is the easy part, put it inside or paint it green and
stick itin a tree. I'm afraid you're going to have a harder time hiding
your tower. But if you do find a way, please let the rest of us know.

I hid mine by putting it in the attic. Unfortunately, it was outside before,
so the neighbors still know where the rfi is comming from.

> I also need ways to hide a antenna tower

That's a bit tougher, but here goes: They put a cell tower down the road in a
Church parking lot. They were told no antenna towers, but a tower disguised as
a flag pole was just fine. We now have a 100' tall and about 8' diameter flag
pole. That is the fattest flag pole I have ever seen. Old Glory flies proudly
from the top, and everyone appears happy, especially the Church, which is
renting the space for the cell tower. We hams thought we were the only ones
using flag pole stealth antennas.
Good luck hiding your tower.

Hi Julian,
try your local "junk yard" or politically correct, your recycling
center. They should have lots of pipe around cheap. You could also
try a plumbing contractor, they usually have let me take a few better
looking used lengths of water pipe for free. It will support the wire
and a lot more. Give it a few raps with a hammer to dislodge inner
deposits and a quick rub with abrasive, prime it and paint it any
color you want, or just leave it au natural. Cheap and effective.

>Nope, I'm limiting the example conditions to satisfy typical ham conditions.<

When did the behavior of mixers become "atypical"?

Here's an everyday hamish set of conditions (let's see if I understand the process using my hammy logic). I have a 25-watt carrier which I AM modulate to 100% with my little 12.5-watt watt modulator. This causes the voltage on positive voice peaks double and the RF output power to hit 100 watts PEP into my 50-Ohm load. Should my hammy logic tell me this feat impossible to achieve because I only have 37.5 watts available?.

When a single pre-mixed waveform is fed into a linear system, the Cecil plan works (if I want to run 25 watts on AM, I've got to have a 100 watt linear amplifier to reproduce the waveform). Mixing and combining signal, on the other hand, isn't a linear process--unless the rule somehow changes when signals are in phase and on the same frequency.

Maybe I shouldn't have said energy. The 2 backward-traveling voltage
waves cancel at every point on the section of coax, leaving zero
voltage. The same happens with the 2 backward-traveling current waves,
leaving zero amps. There is no power flow toward the source.
However, the source produces 100 watts which is delivered to the load.
There's your conservation of energy.

> > > As you say, Component #2 and Component #8 cancel, i.e. engage in destructive

Now look who stepped in the cow pie. This has absolutely nothing to do
with conservation of energy. Field contributions from different parts
of the antenna arrive at a point in space. If they just happen to have
phase values that are 180-degrees opposite, then there is a
destructive interference, or cancellation. That does not mean that the
energy gets magically transported to some other point where they add.
An antenna has gain because field contributions at some other point in
space have phase values that are identical. In this case, there is a
constructive interference, or addition.

I think you're reading something into conservation of energy that is
not there.

Who violated it? Partial reflection/transmission completely modeled
your problem exactly as it should have. 100 watts supplied by the
source, 100 watts delivered to the load. No predicted power on the
coax. 73,
Bill N3WK

I've seen cellphone towers disguised as trees. Unfortunately, they were
20 feet taller than any of the other trees.

Ed -

Let me know if MFJ/HyGain does not supply data in 2 weeks. Based on ARRL efforts to get PRB-1 extensions passed, if MFJ does not supply data -- then a request could be made to ARRL to stop accepting full print advertisements in QST.

Of course it does, Bill, but it is not magic. It is the LAW of physics. If energy disappears at one point because they are 180-degrees opposite, that same energy is *FORCED* to appear somewhere else. That's what the conservation of energy principle is all about. Every case of destructive interference in one location results in a case of constructive interference somewhere else. I am absolutely appalled that you, Steve Best, and Jon Bloom don't understand that law of physics.

> I think you're reading something into conservation of energy that is

Feel free to review the conservation of energy principle, Bill. You followed me down the path of component energy. Now you have to live with the consequences. This stuff is intuitively obvious to me. Maybe I need to write a QEX article entitled, "What Really Happens to Reflected Energy".

What it feels like to me is that you guys are defending an RF Good Old Boys Old Wives' Tale. Please tell me that isn't true and you would be interested in alleviating your ignorance with the truth/facts.

The current Radio Shack catalog has telescoping metal masts in 19' and 36'
heights. The current ARRL Antenna Book has a 42' A-frame wood mast you could
construct from 3 pieces of pine.

Since guy "wires" are cheaper than pine, I like two 2x4's bolted together for the bottom part plus a single 2x4 for the top part. Treated wood lasts a long time when buried at the base. If a little extra height is needed, extend a 2x2 from the upper 2x4 or use fiberglass poles.

When I lived in Tucson, there was one nearby which was disguised as a
saguaro cactus. It wasn't cheap, however. The funny thing was that
there were two undisguised cell towers within 150 feet.

Pardon the ignorance, Cecil, but I'd like to ask you a question. Power, which is
what you like to add together as if you could apply superposition to it, is defined
as a time rate of change of energy. Could you tell me where I could read about

the principal of the conservation of rate-of-change of energy? I've read a few physics
books, and they all discuss the conservation of charge and the
conservation of energy and such, but none of them says anything about the conservation
of rate-of-change. If this is something new, I'd like to know about it.
Thanks.

> you are expected to behave yourself and keep your fingers out of your
nose.
>
> Rick K1BQT
[snip]

No one that I recall ever blasted Chip et al for "new ideas". What was
"blasted" and what deserved to be
blasted was the blatant abuse of USENET NG's to promulgate half-truths about
the supposed advances in Science!

About the only thing that was "new" that Dr. Cohen a.k.a. "Chip" et all have
introduced is nothing more nor less than
the application of the already known methods of mathematical optimization,
known as Genetic Algorithms "GA" coupled
the already known techniques of Simulated Anealing "SA", wherein fractal
geometries are used to generate the
"pattern searches" for the search patterns in the design optimization of
antennas.

Certainly no new "Electromagnetic Science" was developed by those
protagonists [Fractal Electromagnetics, heh, heh??],
rather they have, dare I say "merely", applied an already well known method
of mathematical optimization, to the design of
antennas which are completely characterized by the nearly 200 year old
science first fully elucidated by James Clerk Maxwell.
In the application of GA and SA to antenna design, they "might" be the
"first" to do so, but that is a breakthrough only in the
application of already well known methods of mathematical optimization, to a
new application domain [antennas]. And still
ther was never any attempt to prove or show that the resultant designs were

globally optimum or even better than other
nearby local optimum designs.

The "bombatic misuse" is found in their attempt to convince those not
familiar with methods of mathematical optimization that there
was something "new" in the antennas themselves. Whereas it was only the
design method that was new. It is easy to "blind em with
Science" when the readers are simple ham radio USENET NG participants, or
others without prior experience, training or knowledge
of the well known methods of mathematical optimization. Such methods have
been widely used in many other fields, such as the
design of VLSI circuit layouts, the design of entropy compression codes for
images, etc... What the "fractal electromagnetics"
protagonists have done is to apply these already well known methods to
antenna design.

What they have done is nothing more nor less than the application of well
known mathematical optimization techniques, already developed
for applications in other fields, to the design of antennas. And... they
have *never* shown or proved that their chosen methods of
optimization are guaranteed to produce a global optimum, or even to be
better than the results produced by other methods of mathematical
optimization.

There was never any attempt by the protagonists, but lots of false claims to
the contrary, to prove that their design methods, or final designs
were better [more optimum?] than any other approach to the mathematical
optimization of antennas. This was certainly made clear by Steve
Best when he accepted the $1000 Challenge and quite easily generated antenna
designs using "random" pattern search methods, with
performance, on already agreed figures of merit, that exceeded those
obtained by the fractal search methods of mathematical optimization.
Steve Best has shown that the "optimum" designs obtained by the fractal
methods of searching are at *best* merely "local" optima, which are
not as good as other nearby "local optima" and certainly not global optima!

In summary, the only thing that Chip et al have shown with their fractal
antenna work is that it is possible to use fractal mathematics
to generate the sequence of antenna designs, within a conventional
mathematical optimization loop, to be searched for a "local"
design optimum. As such... it is an "interesting" application of known
methods of mathematical optimization, but not a breakthrough
in electromagnetics.

The attempts to throw others off the track and claims of "intellectual
property" protection which go far beyond the simple
copyright or patent of a given antenna design [A design patent rather than
a concept patent] are absurd to say the least.

But... Hey... this is America... if you can fool some of the people some of
the time then you have the right to go ahead... but those who
are knowledgeable of the methods of mathematical optimization and of the

working principles of antennas were not, and are not,
impressed one iota, notwithstanding such absurd claims.

And so... Art Unwin... Fractal Antennas do not violate, or improve upon, any
of the well known Physics of electromagnetics, what they
are is simply the result of applying a mathematical optimization technique
to the design, i.e. a tools and methodology of design application.

For those who might be interested in learning more about the generic methods
of mathematical optimization which can be applied to
many application domain areas see the mathematical optimization decision
tree at the URL below.

Bravo Doc... That's the basis of the several hundred year old "Scientific Method". Go scientific method! Let's not discourage rational po poohing!

The Scientific Method is not crucification! Rather it is a method of validation of ideas.

For those small dogs who decry the questions recall the small dog in the scenario, "If you can't run with the big dogs then stay on the porch!"

The world of Science is, and has always been, populated by big dogs who have the God given right to challenge assertions and ask questions, regardless of the "qualifications" of the protagonists.

Such questioning must never be repressed!

Best,

As in *Standing* Wave Ratio (SWR).

I'm starting to come around. If you send out 100 watt pulse while the previous one is headed back from a reflection, you could have two 100 watt pulses in the same line.

This reminds me of a previous thread where everyone finally agreed that EM waves E and H fields both pass through zero at the same time, and then they reappear.

> extra frequencies when excited.

Is statement # 5 correct or incorrect as it stands, disregarding
jumps or conjecture as to how it is applied ?

I would rather consider the the correctness of the basic
physics rules rather that shooting all different directions
regarding the correctness of application. I was asked by someone to
dish this thing out at ONE portion at a time. If we don't it it will
lead to total confusion among the many on this thread and the silent
readers that are watching. Once we get an understanding of the basic
principles that I have applied in my work we can then determine if my
use of these laws are used correctly by me or not.

Everybody has a picture of the antenna, so when we agree on the first part we can then debate the antenna ONE step at a time. This will not satisfy all but overall I believe the request to be a good one and thus I will try to follow it so that all are on the same wavelength. You might want to model it as we go along which will give insights to the antenna which we can refer to at a later date.
Bearing in mind that many say they 'just can't follow' this thing, a fresh start
is in order with the first part focussing on the laws of physics as stated to see if the basic statements are correct or incorrect which may or may not
spiral off to a more indepth discussion before moving on. At least we can start off with a program that all can follow.

I have made arrangements to have a 'news' article placed on the net regarding this antenna. It was thought it may that in some way promote the thing, but at the last interview I said to the reporter that I felt the topic will not be of interest to his readers which to my surprise he turned to me and said
"Art, this is NOT about antennas, this is about YOU".
Some may find this of interest as many others did who contacted me from as far away as a ham in Colorado and the East Coast. It shows a photo of me that was touched up to remove the horns!
I will give the URL out tomorrow or the next day as I have to Fed X the article
to my son in San Diego to do what needs to be done.

Hi Bob,

The company that does this stuff is The Larson Company.

http://www.larson-usa.com/index2.html

follow the link to the Camouflage Division.

These guys are masters at fake rocks, etc. Many of the road projects
in Tucson, particularly in the high rent districts use Larson (or
thechniques they developed) to hide the ugly cuts in the banks along
the road.

The world famous Arizona-Sonora Desert Museum creates a lot of their
exhibits with the same techniques.

Tom, what do you think the joules in joules/second represent? We are talking
about energy. Nobody is trying to conserve power. If you believe that
75 joules/sec + 8.33 joules/sec = 133.33 joules/sec then all you have to
do is multiply both sides of the equation by one second to get
75 joules + 8.33 joules = 133.33 joules

Now seriously, do you really believe that doesn't violate the conservation
of energy principle?

Richard Clark wrote:
> Look at Bart's thought experiment posted recently.

Bart seemed to say we cannot have three or four transformer secondaries driving 50 ohm loads while the primary sees a 50 ohm load. 60 Hz power engineers have been doing that for over a century. The equation that has to be satisfied is:

Vin^2/50 = V1^2/50 + V2^2/50 + V3^2/50 + ... or

Vin^2 = V1^2 + V2^2 + V3^2 + ...

To me, those conditions seem relatively easy to satisfy even though those voltages are not orthogonal to each other. Seems to me, this is the equation that a transmission line must satisfy to avoid violation of the conservation of energy principle (which any power engineer will tell you is not under the control of the whims of RF engineers).

>

Cecil,

I'm not missing anything about your argument. I think you're mistaken about the relationship between the superposition of forward voltages and currents and the law of conservation of energy. Two forward voltages in a transmission line add as vectors such that Vtotal = V1 + V2. The total forward power is simply determined from |Vtotal|^2 / Zo, presuming that Zo is a pure resistance. The law of conservation of energy requires that the total power delivered by the source to the line is equal to the total power dissipated in the line. Additionally, the law of conservation of energy requires that the total power flowing into a junction equals the total power flowing out of the junction, presuming no power is dissipated at the junction. There is nothing in my statements that is inconsistent with these basic facts.

You don't believe that two voltage waves can add such that the resulting power in the total wave is greater than the sum of the individual wave powers, when these are considered separately in the line. I can demonstrate this fact with any example you chose. Not accepting this, you are somehow trying to explain where the missing power comes from as if its re-reflected or redirected from somewhere else. It just does not happen that way. Voltages and currents add and subtract at every point and load in the line resulting in a total power.

Art, KB9MZ wrote:
"When you say "story" are you refuting the correctness of #1?"

No slam intended. "Story" is shorter than "process" by two letters. There are true stories as well as false. Short words clarify presentation if well chosen. I may have made a poor choice if #1 is correct. "Story" was not meant to be derogatory.

Nw If Art really was implying a heterodyne process without a mixer, I say it does not exist.
#1 would be irrelevant.

Art also wrote:
"Is statement #5 correct or incorrect as it stands---?"

I don`t know what #5 means. A coupled structure will produce a null in conjuction with another radiator. The depth and direction of the null(s) are dependent on amplitude and phase of currents in the radiator elements. Art offers two possibilities in #5. The first is incomplete because a null is offered as the only outcome. The other possibility relies upon F1 and F2 producing F3 which is nonsense.

Best regards, Richard Harrison, KB5WZI

O.K. Cecil, lets say you're right and 75 joules/sec + 8.33 joules/sec = 83.33
joules/sec.
Since voltage is proportional to the square root of power, what you're saying
is that
sqrt(75) + sqrt(8.33) = sqrt(83.33), or, 8.6603 + 2.8862 = 9.1285, which, of
course, is wrong.
Since voltage is supposed to obey the rules of superposition, what
you're really doing is denying the linearity of Maxwell's equations upon which
this whole
electromagnetic edifice is built. Hey! Maybe you're right, and Maxwell and the
rest were
wrong. The next step is figuring out a way to convince us - who were
brainwashed by the textbooks - of the truth of your interesting ideas.
Good luck!

Tom Donaly KA6RUH

(P.S. To forestall a stupid blast from Reg, let me state that Maxwell's
equations were

supposed to have originally been called the Heaviside-Herz equations.)

Have you referenced Bill Klocko's posting and my response? He broke the waves down into components.

106.066 volts at 0.707 amps
106.066v/0.707a = 150 ohms
106.066v * 0.707a = 75 joules/second in that wave

35.355 volts at 0.236 amps
35.355v/0.236a = 150 ohms
35.355v * 0.236a = 8.33 joules/second in that wave

Adding those two waves:

106.066v + 35.355v = 141.4v
0.707a + 0.236a = 0.943a

141.4v/0.943a = 150 ohms
141.4v * 0.943a = 133.33 joules/second in that wave

Let's look at one second of this dynamic energy movement. Are you really saying that you can turn 75 joules plus 8.33 joules into 133.33 joules? Steve, where is the missing 50 joules?

Cecil,

This is a seriously disappointing comment from an electrical engineer.

Where in the world did you ever get the idea that a power source can simultaneously force both voltage and current "no matter what the antenna impedance or SWR"?

[SWR not relevant here]

Since you have postulated that the system is otherwise lossless, such behavior would be a flat-out violation of Ohm's law.

You have created physically impossible assumptions for your model. Any subsequent analysis is likely to be nothing but noise.

And a final comment for the benefit of CW (Clinton) --- Over and out.

73,
Gene, W4SZ

Egads Tom, where did you learn your math? The sum of the square roots of
two numbers is NOT equal to the square root of the sum of the numbers
unless the numbers are unity.

The correct equation is sqrt(75 + 8.33) = sqrt(83.33) which is correct.
Square roots do not obey the distributive law of mathematics.

Consider the equation A + B = C

sqrt(A + B) = sqrt(C) is correct, sqrt(A) + sqrt(B) = sqrt(C) is incorrect.

It is true that 106.066^2 + 35.355^2 = 111.8^2 where

106.066^2/150 = 75w, 35.355^2/150 = 8.33w, and 111.8^2/150 = 83.33w

Question: What impedance does an antenna tuner present to a transmitter?
Answer: a constant 50 ohms.

Question: What voltage does a 100w transmitter deliver to a constant 50 ohms?
Answer: a constant 70.7 volts.

Question: What current does a 100w transmitter deliver to a constant 50 ohms?
Answer: a constant 1.414 amps.

The antenna tuner presents 50 ohms to the transmitter no matter what
the antenna impedance or SWR. Do you really disagree with Ohm's law?

I'll admit I must have been asleep the day the prof covered energy.
Nevertheless, let me see if I understand what it is you're saying
here. Suppose there's an antenna pattern with a deep null at a certain
angle. Are you saying that the energy that would have been at that
angle represents a loss of energy in the system? Are you also saying
that the energy taken out to form the null must then be inserted
somewhere else in the pattern to compensate? I can see energy being
lost through attenuation. I can see energy increasing because of some
net inward energy flow (an additional source). I can also see energy
oscillating between electric and magnetic. In the case of the pattern
null, I just don't see it. If it's a 40-dB null, does 40 dB get added
to a lobe? Where does the energy go - to the next lobe over, or the
next lobe inward?

Let's go back to your simple problem. You're saying that the energy in
the cancelled backward-traveling waves also represents a loss of
energy in the system, and that the energy in the cancellation effect
joins the forward energy on the twinlead. Why should this energy
appear on the opposite side of the coax-twinlead junction? Why should
the energy flow all of a sudden reverse direction?

I still think you're reading more into the conservation of energy
principle than is intended. 73,
Bill N3WK

I made a homebrew 80-10 antenna from an old firestick cb antenna. Normally, it would be tuned to 11m. I cut the winding out in the middle of the stick and replaced with a much larger loading coil. I made the coil on a plastic form, and put end caps on it so the stick would fit though the middle. The stick itself is 5 ft tall. For 80 and 40 meter use, the large coil is used with a 4 ft stinger whip attached to the top of the stick. "9 ft total" There is a single tap for 40m, and I have 3 taps for 75m, depending on the freq I want to use. For 30-10m use, the loading coil is bypassed with a wire and clips, and the stinger is varied for each band to tune. 20m uses about 2 ft of stinger. 10m, about 3 inches or so. I keep a selection of stingers to select from. You do have to get out to change bands, but it only takes a couple of minutes to change. I also can use a 3 ft mast under that antenna for a total height on the low bands of about 12 ft. But I usually only use that when parked to avoid whacking it on trees. One advantage to this setup is the light weight. I get bugcatcher performance at a fraction of the weight a "real bugcatcher" would weigh. So that makes mounting much simplier. The antenna didn't cost me a dime as I had all the junk ready to go. I also have a 6 ft 20m hamstick that I use on 40m with a 4 ft whip. "10 ft total" It works very well. Just as good as my fat coil antenna I think. 20-10m is very simple. Just get a single 10m hamstick, and then get extra stingers for each higher band. IE: appx 2 ft or so for 20m, 1.5 ft for 17m, etc, etc. Will depend on the stick used. A cheap and easy way to work the higher bands with a slim and very light antenna.
And it will work very well. On 20m, it's more efficient than a 20m hamstick would be on 20, due to using extra capacitive loading instead of inductive. With my all bander on 20m, which is about 7 ft tall on that band, I've worked all over the world with results that make you think you are at home instead of a car. 20m mobile is easy unless you have a real dog of an antenna. But I actually work 80/40 most of the time mobile. The fatter 80/40 loading coil brings me up to the "bugcatcher" level as far as performance on those bands with the standard 9 ft antenna I usually use when driving. I use a small tuner

for impedance matching , which is required on most bands. You can also use caps, and tapped coils like the dollar special matcher in the arrl ant handbook. I'd probably use it if I didn't have the tuner. MK

That's the exact question I asked Cecil sometime ago. I think he actually
believes it magically reverses direction without a physical cause to explain
it.

Cecil, besides your written math, what physical action causes the rearward
traveling energy to reverse direction??

Yes, energy is like the air in a balloon. Squeeze the balloon in one
place and it gets bigger in another. The nulls in an antenna pattern
are the result of destructive interference in the fields. The lobes
in an antenna pattern are the result of a corresponding constructive
interference pattern in the fields. If I remember correctly, the MOM
calculations are based on those destructive/constructive interference
patterns.

> the energy flow all of a sudden reverse direction?

Because it has to go somewhere, Bill, and we know it's not going toward
the source. Since we are dealing with essentially a one dimensional wire,
the energy cannot do anything else except head back toward the load.
Have you taken time to look at the example I gave? When the load is
switched from 150 ohms to 50 ohms the signal generator's reflected
power circuitry stops dissipating 25 watts and the load's delivered
power is increased by 25 watts. How does that 25 watts get to the
load without joining the forward wave?

I completely disagree that 75 joules + 8.33 joules = 133.33 joules
and that's what happens each second in the example. Where does the
missing 50 joules come from? There is not enough energy in your two
waves above to result in the forward wave. You continue to insist on
violating the conservation of energy principle.

You continue to ignore the 50 joules/sec contributed to the forward wave
by the interference pattern. The correct power equation is:

75w + 8.33w + 25w + 25w = 133.33w or

106.066v^2/150 + 35.355v^2/150 + 35.355v^2/50 + (-35.355v^2)/50

The correct voltage equation at the Z0-match is:

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

where the last two terms in the summation are the voltages involved
in the interference pattern.

How you can maintain that 83.33 = 133.33 is beyond belief.

You haven't answered my other question about how 25 watts makes it
from the source to the load without joining the forward wave. Are
you just going to ignore that question and hope I forget about it?

Tom, KA6RUH wrote:
"Power, which is what you like to add together as if you could apply superposition to it, is defined as a time rate of change of energy."

Yes, and that change may be in placement, joules per second past a point (a joule is a watt-second, and a watt is a coulomb per second), or a change in state, conversion to heat for example. Whether we work with joules or joules per second is irrelevant.

Power is convenient to use because we can easily measure it and it can be added and subtracted. We assume for practical purposes that the power taken from common transformers equals what is put in, and we can use turns ratios and impedance ratios.

Bird tells us that power delivered to the load is simply forward power minus the reflected power. There is no space in a transmission line for much long-term storage, so the power to the load equals the power delivered by the transmitter in the usual case of insignificant line loss.

Some are questioning a null in radiated power in some particular direction causing a boost elsewhere. Knowledge of the mechanism isn`t necessary to prove the redistribution. All the poweer is radiated for practical purposes. If it doesn`t go one place then it must go elsewhere, and it does.

Real power in a transmission line is either coming or going and it adds or subtracts. This is much simpler than toying with the interference patterns or figuring the impedances produced by wave interference.

Best regards, Richard Harrison, KB5WZI

Steve, we have been over and over this point. Anytime there is a destructive interference, there is a corresponding constructive interference. When the medium is a wire with only two directions, a destructive interference pattern in one direction always causes a constructive interference pattern in the *only* other direction. Since we know the destructive interference pattern stops the reflected energy from flowing toward the transmitter, the constructive interference pattern causes that amount of energy to flow toward the load. It has no place to go except join the forward power. It cannot stand still. If it is not flowing toward the source, it is flowing toward the load and you are completely ignoring it.

> Cecil, besides your written math, what physical action causes the rearward
> traveling energy to reverse direction??

For the umteenth time, destructive/constructive interference. Bill calls it cancellation. The voltages cancel and the currents cancel but the energy cannot cancel and cannot go anywhere except toward the load. You are continuing to ignore the 50 watts involved in the interference pattern. According to Bill's own calculations, the two voltages are equal to 35.355v and opposite in phase. The two currents are equal to 0.707a and opposite in phase. That's 25 watts apiece according to Bill's calculations. (Component #8 in his posting)

The power discussion in your example does not even closely represent whats
happening. Your example requires us to believe that when the source is
connected to a matched load there is no internal power dissipation.

Start the example with a 141.42 V source with a 50 ohm source impedance, as
I did in the other thread, and lets have the same discussion.

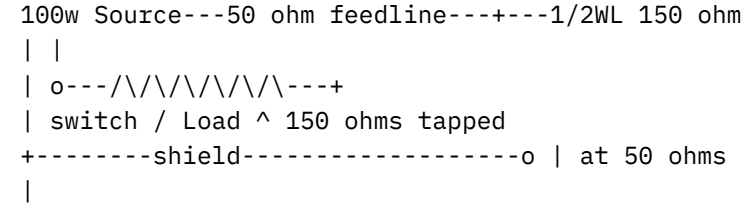
I am not talking about internal source dissipation, Steve. You apparently
are not familiar with a signal generator that has a circulator which routes
most of the reflected power to a resistor. It's the reflected power load
resistor in the signal generator that I am talking about. The internal
power dissipation of the source is irrelevant. The signal generator puts
out a fixed 70.7v at 1.414a into 50 ohms and dissipates all the reflected
power it receives.

It is apparent why you don't want to discuss this example because it would
prove you absolutely wrong once and for all.

> Start the example with a 141.42 V source with a 50 ohm source impedance, as
> I did in the other thread, and lets have the same discussion.

Nope, you first. Here it is again.

The following example is driven by a signal generator which contains
circuitry that causes all reflected energy to be dissipated. Except
for the dissipation in the signal generator and the load, the system
is lossless and there are no common mode components. The source
impedance and the efficiency of the signal generator are irrelevant
as the signal generator outputs a constant 79.7v at 1.414a into 50
ohms and dissipates all the reflected power it sees.



o----------+

With the switch in the 150 ohm load position, there is 100w of forward power on the 50 ohm feedline. There is 25w of reflected power on the 50 ohm feedline that gets dissipated in the signal generator. The forward power on the 150 ohm feedline is 75w and 75w reaches the 150 ohm load resistor because there are no reflections from the 150 ohm load.

Now the switch is thrown to the 50 ohm load position. The forward power on the 50 ohm feedline remains at 100w but now there is no reflected power on the 50 ohm feedline so there is no dissipation of reflected power in the source. We now have 100w reaching the 50 ohm load resistor. The power dissipated in the source has decreased from 25w to zero watts. The power in the load has increased from 75w to 100w.

The question is: How does the 25 joules/sec get from the source to the load without contributing to a component of forward voltage and current on the 150 ohm feedline?

VE9SRB wrote:
> Do you agree or disagree with the following statement: 106.066 V forward +
> 35.355 V forward equals 141.421 V forward?

I agree with it but you have omitted two voltage terms. The equation should be:

106.066v + 35.355v + 35.355v - 35.355v = 141.421v

where the last two terms in the summation are the two voltages that cancel during the interference pattern at the Z0-match. Since they cancel, they can be dropped from the equation to obtain yours. But they cannot be dropped from the energy equation because their energies don't cancel. The energy cannot go to zero like the voltage and current can.

The balanced energy equation becomes:

106.066v^2/150 + 35.355v^2/150 + 35.355v^2/50 + (-35.355v)^2/50 = 141.4v^2/150

or 75w + 8.33w + 25w + 25w = 133.33w

All perfectly consistent with no need to violate the conservation of energy principle.

> --
>

Its already in the 100 W of forward power to begin with. There's nothing special going on here Cecil. The total power delivery in both examples simply occurs as a function of what happens to the 100 W of forward driving power. Its the only power that matters.

In one case (150 ohm load), the 100 W of forward power arrives at the load where 75 W is dissipated and 25 W is returned to the source. The forward power in the 50 ohm line is 100 W and the reflected power is 25 W. The total power dissipation in the two loads is 100 W

In the second case (50 ohm load), the 100 W of forward power arrives at the load where all of it is dissipated - the 25 W of reflected power simply no longer returns to the source. The forward power in the 50 ohm line is 100 W and the reflected power is 0. The total power dissipation in both loads is 100 W.

The only question to consider here is what happens to the 100 W of forward power driving the line. Its the only forward power to consider. When you throw your switch, the 25 W of reflected power simply stops going back towards the source. This is an extremely simple concept. Your incorrectly trying to relate power distribution at T- (before the switch is activated) to T+ (after the switch is activated).

What's the point to this example as it relates to multiple wave addition?

If you really want to understand the concepts associated with adding multiple voltage waves and the resulting total power try this example:

141.421 V -- 50 ohm source Z -+----150 ohm line 1 WL ----+-50 ohm load

Determine the initial conditions in the source and in the line.

Determine the steady state conditions in the source, in the line and the load.

Now examime the initial and re-reflected forward waves in the line and determine all of the power relations.

Even if the old work is found, it is of limited value. Because the way
to calculate wind action on a self-supported tower has changed over the
many years that the device has existed, a new calculation is desirable.
Zoning boards (yes, even in fly-over-country) tend to have at least one
person who wants the building code to be followed and who expects to
have the seal of an instate P.E. on the papers certifying that the
structure conforms.
Objective and uniformly applied building codes are unlikely to be
put aside by Federal law and are unlikely to be overlooked by local
authority. A zoning ordinance that prohibits a lawful activity is
another thing altogether.

I find the rubbery antenna that comes with the Icom R2 scanner too
short for good reception. But, most other longer antennas just won't fit into
the screw of the scanner. Is there any gadget that will connect another
longer antenna (possibly just a hollow metal tube) with the screw of
the scanner ? Or are there other ways to improve on the effiency of
the existing rubbery antenna ?

Thank you

Message-ID: <db35a0c.0208112036.3c737dbd@posting.google.com>
Source record: 137113

Hi,

Since a few weeks I try to find on several websites technical data
about 5/8 vertical for the 80/40-10m (and possible WARC) but I can no
more find any antenna of this type (Ushler, Maco, etc). Have they all
been discontinued ?
It is a pity as height enough and with their radian they give a
appreciate gain vs the isotropic (2 lobes)...

Where can I buy a good 5/8 vertical nowadays ? Have you some
brands/models ?

Thanks

Thierry

Nope, that's not true. There are no reflections from the 150 ohm load. I'm
beginning to realize that you don't even read my postings.

Nope, the second case is our old friend 75w + 8.33w = 133.33w. 133.33w
arrives at the load and 33.33w is reflected. I don't know why I bother.
You don't seem to comprehend anything I say.

The 150 ohm resistor first dissipates 75 watts. The 50 ohm resistor then dissipates
100 watts. That's a difference of 25 watts. Where is that 25 watts in your equation
of 75w + 8.33w = 133.33w?

You don't understand. The number proportional to the 75 watt wave is 8.6603.
The number proportional to the 8.33 watt wave is 2.8866. If you are a believer
in
superposition, you will believe that when you add the voltages in phase you
will
get 11.546, of which the square is 133.32. If you do it your way, the voltages
in the
two waves will have to magically change value thus violating the law of
superposition.

No, Cecil, you have two voltages, in two waves, each proportional to the square
root of
its respective power. You add the voltages according to superposition and you
get 11.546. Square that number and it gives you 133.32. If you insist on

adding
the powers as if superposition applied to them and then taking the square root
you'll always get answers that other people will find hard to believe. Didn't
they
teach you in elementary electronics class that superposition doesn't apply to
power? This is a classic example of why it doesn't.

Square roots do not obey the distributive law of mathematics. If A + B = C,
the square root of A plus the square root of B never equals the square root of C.
Your mathematical concept is flawed. If A^2 + B^2 = C^2 and then you try to say
sqrt(A^2) + sqrt(B^2) = sqrt(C^2) then that is a math violation. What we are
discussing is irrelevant to your mathematical error.

> >of
> >> course, is wrong.

I think I understand what you are saying now so let's try it again. The
above formula is well known to power engineers. Let's say we have the
following circuit.

9.1285 volts on the primary of a transformer with an input impedance of 10 ohms.
8.6603 volts on a secondary of a transformer with a load of 10 ohms
2.8862 volts on a secondary of a transformer with a load of 10 ohms

Power in equals 9.1285v^2/10 = 8.33 watts
Power out from 1st secondary 8.6603v^2/10 = 7.50 watts
Power out from 2nd secondary 2.8862v^2/10 = 0.83 watts

8.33 watts = 7.50 watts + 0.83 watts

What this proves is that if Steve omits the 50 watts from the interference
pattern, his 106.066v and 35.355v won't add up to 141.4 volts. You simply
cannot get 133.33 watts from the combination of a 75 watt wave and an 8.33
watt wave.

>watt wave.

Hi All,

Another
>formula ... well known to power engineers
or specifically, "Reference Data for Radio Engineers," "Magnetic-Core
Transformers,"

Ns / Np = ((Rs / Rp) * (Ws / Wp))^ï¿½
where
N : turns

R : resistance
W : power
E : voltage
p : primary (one of two)
s : secondary (one)

When you substitute all values offered by Cecil, above, into this
equation everything balances (in a manner to be shown, following).

Cecil's model can be used to examine his statement
>You simply cannot get 133.33 watts from the combination
>of a 75 watt wave and an 8.33 watt wave.
through a simple inversion of secondary/primary and a promise to
deliver 13.33 watts (continuing the metaphor of his example):

Power out equals 11.55v^2/10 = 13.33 watts
Power in from 1st primary 8.6603v^2/10 = 7.50 watts
Power in from 2nd primary 2.8862v^2/10 = 0.83 watts

Ns / N1 = ((10 / 10) * (13.33 / 7.5))^ï¿½
Ns / N1 = 1.333

Ns / N2 = ((10 / 10) * (13.33 / .83))^ï¿½
Ns / N2 = 4

for a sanity check, compare the ratios to the known voltages (also
performed and passed employing Cecil's configuration):
Ns / Np = Es / Ep

Ns / N1 = 11.55 / 8.6603
Ns / N1 = 1.333

Ns / N2 = 11.55 / 2.8862
Ns / N2 = 4

Looks like Steve's answer works just as well as yours Cecil (something
I've said all along - you two guys are arguing in different
universes).

Well, let's see. There's one of three possible explanations:
1. I've dicked up the math somewhere;
2. It works for both of you;
3. _____________ (a popular choice, in the class of what is the
definition of "is?")

> Best regards
> Art Un win KB9MZ

Dunno Art, I think it's the other way around. You are giving us hoops
to jump through. I was looking at your webpage and the ZZ1 antenna,
And I'm still not sure what you are using. From that picture, it looks
like you have two dipole elements, each with a cap. Is that right? I
modeled only a single dipole element. I never remember you mentioning
using two dipole elements. You mention two caps in that ZZ1. I never
modeled two caps, much less two parallel dipole elements. I then read
through the text on the website, and I still end up basically confused
as there is no real description of a particular antenna. You talk of
adding a second element. All this time, I thought we were using a
single dipole element? I haven't seen your patent, as I don't ever
remember seeing a link, or a name to look up for it. So I don't know
about the others, but at this point, I'm still confused as heck about
what antenna you are even talking about. The AO list does not do me
much good at all, because I don't have AO. Does the patent have a
decent picture to where I can see exactly what you are talking about?
You are making us jump through hoops, Art. Yes, two parallel dipoles
can be steered. But all this time, I thought you were talking about a
single dipole element. When I first saw the ZZ1 antenna, I thought you
were drawing two pictures of the same single element but with
different views..But, now I'm not so sure.
It seems to me it would have been much easier for you if you modeled
this yourself using a popular program such as eznec, even if you had
to get someone else to do it for you. That way, you can hand out the
ez file, and everyone can see the antenna, and see for themselves how
it models, and judge if it's accurate, or even make one themselves to
try in the real world. There would be no confusion as there is now.
But, you are wanting us to do this, "I've made two already myself",
and I still don't know for sure what in the heck I'm really supposed

to be making. I don't mind modeling something, but it's a waste of my time to keep modeling the wrong antenna. I can't read your mind. You need to get your ducks in a row first. That way you can debate the thing in an orderly military manner. It's more like helter skelter the way things have been going. I hope you take this as friendy criticism...No flaming intended. MK

> transmission line with equal and opposite currents in each leg?

Yes, but not an ideal one. See below.

And would
> not all radiation be essentially cancelled?

The fields from the two wires would very nearly cancel. But for a given power input, the fields would be huge (due to heavy currents due to mutual coupling). So the radiation would be pretty normal if the losses could be kept reasonably low. With the wires that close, though, it would actually be impossible to keep losses really low.

> What happens to the power applied in this case? The line termination is a
> direct short which would produce total reflection and no power would be
> accepted by the antenna to be radiated. Hence, no conflict with
> Conservation of Energy.

Even if you had lossless wires, you wouldn't see a short circuit looking into the input. There would be a small but finite value of resistance. This is the radiation resistance, and it would be present because of the fact that the parallel wires will radiate. (Only in a perfect and lossless coaxial cable, or other fully shielded transmission line, would the input resistance be zero. As long as fields can escape, the resistance will be finite.) If you were able to match your transmitter to that resistance value, all the power you applied would be radiated. The currents in the wires would be very large, resulting in a very large field from each wire. The sum of the fields, while only a fraction of the field from each wire, would be comparable to that from a normal dipole.

I sent George an example EZNEC file, of two parallel wires 4 inches apart at 14 MHz. The feedpoint resistance in this case is 0.02683 ohms

-- very small, but finite. A power of 100 watts would result in a feedpoint current of 61 amps. Interestingly, the pattern is isotropic. Introducing a realistic loss of #12 copper wire reduces the field strength by 15 dB, underlining the practical limitations of loss and the impracticability of this as an antenna.

> As the ends of the legs are moved apart, a real component in the driving
> point impedance is developed and power begins to be accepted and radiated -
> all of it, as you point out - in some field form or other.

There's no magic point where this occurs. The real component is present down to the smallest spacing you'd like. Of course, it gets arbitrarily small as the spacing gets arbitrarily small.

But if you did have a perfectly shielded pair of wires, where the fields were confined by the shield and not allowed to radiate, you'd have zero input resistance regardless of the spacing or the wire length. With zero input resistance, no power could be applied to it.

> As the spacing increases until it reaches 180 deg, the driving-point
> impedance becomes whatever it is for that piece of wire at that location.
> And the real part will accept power and it will be radiated in the manner
> of the dipole it has become.

I keep stumbling over this "accept power" phrase. Any antenna with any finite radiation resistance will "accept power". If you restrict yourself to connecting a 50 ohm fixed impedance source to the antenna, then yes, the amount of power you get to the antenna -- the amount it "accepts" -- is strongly influenced by the feedpoint impedance. But if you have the ability to match the antenna (as I assume is generally the case), then all antennas will "accept power". As the spacing increases, the real part of the resistance increases, and you have to adjust your matching network. That's all.

I don't want to minimize the practical limitations of getting power to an antenna with a very small radiation resistance, or the very real losses that will occur in such an antenna. In fact, I don't think antennas with these characteristics are generally a good idea because of the practical problems involved in feeding them and keeping losses manageable. My only point is that if an antenna with close spaced and out of phase wires doesn't work well, it's not because the fields are cancelling and the power therefore mysteriously disappearing. Field cancellation commonly occurs, and ones with pretty severe field cancellation, such as the 8JK, can actually have useful gain.

> Anywhere close? <:}

Sure, very close. And I've really liked the other postings you've made. They're right on the mark.

2683. Re: EZNEC

Newsgroup: rec.radio.amateur.antenna

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D579E82.9070800@eznec.com>
Source record: 137021

EZNEC users who have the resources to accurately measure antenna
patterns have told me they've gotten excellent results for Yagis of more
than 15 elements. A wide variety of other antennas have performed as
predicted.

I wish I could take credit for this, but I can't. It's due to the NEC-2
calculating engine used by EZNEC. This was developed by the government,
not by me.

This isn't to say, however, that NEC-2 and EZNEC don't have their
limitations and don't take a good deal of care and skill in some
situations. And one of the weak points is the ground models. They assume
a perfectly flat ground that's infinite in extent and homogeneous in
conductivity and permittivity. So assumptions about patterns and
performance over real ground have to be made with some care.

The 25 W reflection occurs at the junction of the 150 ohm cable, which is terminated in a 150 ohm load. When you replace this junction with a 50 ohm load, the 25 W reflection simply does not occur, so this power no longer goes to the source. That's what happens to your 25 W - it stays at the 50 ohm load. It no longer returns to the source. Its very simple. There is no 75w + 8.33w = 133.33w equation in this example Cecil. This example has absolutely nothing to do with the situation we have been discussing.

If you want to see an example where we have a 75w wave and an 8.33w wave superimposing to create a 133.33 w wave where there is NO corresponding destructive interference or "power cancellation" take a look at this example - don't keep ignoring it.

141.421 V -- 50 ohm source Z -+----150 ohm line 1 WL ----+-50 ohm load

Determine the initial conditions in the source and in the line.

Determine the steady state conditions in the source, in the line and the load.

Now examine the initial and re-reflected forward waves in the line and determine all of the power relations.

And that's what I've been saying all along, Richard. Steve is arguing
in a universe where the conservation of energy principle doesn't exist.

The junction is NOT replaced with a 50 ohm load and to say it is is just
the obfuscation of a smokescreen. The 50/150 junction has not changed. The
only change is changing the load from 150 ohms to 50 ohms. Please adhere
to the boundary conditions.

> That's what happens to your 25 W - it stays at the 50

Of course it does, Steve, that's why I presented it. You are forced to ignore
it since it would prove you wrong. On the off chance you didn't understand
the diagram or the question, here it is again.

Again the source is a signal generator with a circulator that dissipates all
reflected energy.

Configuration #1

100w source---50 ohm feedline---+---1/2WL 150 ohm feedline---150 ohm load
100w forward 75w forward 75w dissipated
25w reflected 0w reflected
and dissipated

Configuration #2

100w source---50 ohm feedline---+---1/2WL 150 ohm feedline---50 ohm load
100w forward 133.33w forward 100w dissipated
0w dissipated 33.33w reflected

In Configuration #1, the circulator is dissipating 25 watts and the 150 ohm
load is dissipating 75 watts.

In Configuration #2, the circulator is dissipating zero watts and the 50 ohm load is dissipating 100 watts.

The 25 watts that was dissipated in the source circulator in Configuration #1 is dissipated in the load in Configuration #2, i.e. 25 watts has moved from the source circulator to the load simply by changing the load from 150 ohms to 50 ohms.

The question still is: Where is that 25 watts in your 75w + 8.33w = 133.33w equation.

The 75w is the same in both configurations. The 8.33w exists only in Configuration #2. What happened to the 25 watts? Where does 25 watts appear in your power equation? How did that 25 watts get from the source circulator in Config #1 to the load in Config #2 without joining the forward voltage and current on the 150 ohm feedline?

I'm going to keep asking this question until I get a straight answer or you refuse to answer.

From your earlier drawing, I thought that you replaced the 150 ohm line and
150 load with a 50 ohm load. Sorry for the confusion on my part. I'll get
back to you shortly. In fairness, take a close look at the example I posed
to you.

Steve

Probably my fault. That ASCII drawing was pretty busy.

> I'll get back to you shortly. In fairness, take a close look at the example
> I posed to you.

I promise to do that, Steve, just as soon as we are finished with this example. You have a tendency to leave one example unfinished and jump from example to example which only winds up confusing everyone. My original example a year ago used a reflection coefficient of 0.707 which made the math easy. You changed the example to a reflection coefficient of 0.5 which introduced a calculator as a requirement and consumed more time. The simplest examples are the most effective.

> the existing rubbery antenna ?
>
> Thank you

The connector on the R2 is an SMA. There are adapters that lets you use a
BNC connector instead. BNC is a
larger and more convenient connector. One example of what seems to be a good
adapter is : http://www.wa3hrl.com/smabnc/ . Does that seem to fit the
antennas you've seen?

The antenna picks up stronger signals from metal objects if it is placed
nearby. That works especially good on shortwave. Putting the receiver on
some grounded metal chassi seems to help reception generally.

To simply couple a wire of random length to the R2, you can take a plastic
tube, wind and tape one end of a wire on it and then slide this tube on the
rubber antenna. The rest non-wound part of the wire could be a couple of
feet long and hang in the air.

Don't mess with the R2s SMA connector. You want it to last.

Fredrik

> Power in from 1st primary 8.6603v^2/10 = 7.50 watts
> Power in from 2nd primary 2.8862v^2/10 = 0.83 watts

Something's obviously wrong, Richard. Power companies would pay mucho dinero for any transformer that inputs 8.33 watts while outputting 13.33 watts but that's the way it is in Steve's universe. In my universe, the input impedance of the two primaries is not 10 ohms. Satisfying the conservation of energy principle requires the input impedances to be more like 6.245 ohms while keeping the voltages constant and the 10 ohm load constant.

Power out equals 11.55v^2/10 = 13.33 watts
Power in from 1st primary 8.6603v^2/6.245 = 12 watts
Power in from 2nd primary 2.8862v^2/6.245 = 1.33 watts

If the choice is between (balancing the voltage equation and un-balancing the energy equation) Vs (balancing the energy equation and unbalancing the voltage equation), Mother Nature in my universe sez balancing the energy equation is the only rational choice.

The longest transmission lines in the world are managed by engineers who would laugh deliriously at the concept of 75w + 8.33w = 133.3w. One simply cannot add the two and only two components below in a valid manner and obtain these results.

(106.066v at 0.707a) + (35.355v at 0.236a) = 141.4v at 0.943a

Referencing Bill Klocko's posting, there are two more components that must enter the above equation, component #2 and component #8

Assuming the reference is the 100w forward wave with 70.71v at 90 deg accompanied by 1.414a at 90 deg, component #2 is 35.355v at 90 deg accompanied by 0.707 at -90 deg, and component #8 is 35.355v at -90 deg accompanied by 0.707a at 90 deg. Component #2 and Component #8 cancel, but their energy remains. Those 50 joules per second are what is missing from the 75w + 8.33w = 133.33w energy equation.

> good cheap material to act as the mast, that would take the weight of
> the wire?

I use the following setup for a portable/temporary mast

2'x2' square of 1/2" plywood, with holes drilled about 1" in from each corner
4 large nail type tent stakes
old xmas tree stand bolted to center of plywood square
23' fiberglass & aluminium extension utility pole

I just nail the plywood square to the ground (using the tent stakes thru the corner holes), and insert the pole into the xmas tree stand. total cost (excluding the xmas tree stand) was about $35 (most of which was the utility pole). I did need to remove the rubber grip from the base of the pole to get it to fit into the stand, but it works really well, and is easily portable.

Hi, Richard,
I didn't expect to convince Cecil with my simple observation. I merely wished to point out that he could either add powers the way he does, and violate the superposition principle, or he could concentrate on the voltages and come up with a different answer. The transformer example he gave is obfuscation unless he can prove that his transformer is directly analogous, mathematically, and physically, with a transmission line. If it is, then why argue transmission lines when you can argue transformers, which are ostensibly simpler? You're right, Richard, both Cecil and Steve eventually come up with the same numbers, it's the method of interpreting how they were arrived at, and what they mean, that has generated all the verbiage.

If one has a constant impedance which is what my antenna revolves
around
then you wiil always control the electrical lengths of the electrical
length.
****
> By using "switch mode power supply" and "power factor correction"
> techniques, even the input impedance could be controlled.
>That's a neat trick !
>
****

I do not know whether you are pulling my leg or not, but here are my
comments
on what you have written.

ALL multi frequency anteenas should an impedance that is controlled.
A good example is a loop or even a trapped dipole, to not do so
requires extra means to obtain a good/usable SWR.

"Trick" is not what I call a good use of the term. It is done all the
time!
The antenna that I describe revolves around constant impedance and
control of the electrical length, it would not be succesful
otherwise.And as Peter Bracket
stated somewhere, the outcome MUST be predictable both in action and
also on
mathematical ground.(The man must be an engineer) If it is not then
the use of the term "trick" would be suitable.
I say again 'the antenna' is not new, I have invented nothing.All i am

doing is presenting a concept that meets most amateur requirements
Your 'tactical....
antenna seems awfully complex to me. As with the physical shape of 'my
dipole'
and the mathematics that go with it all is simple enough to follow by
all hams who have a basic license. And that's how I like it rather
than vague claims
that are often made by many.
Yes Peter, you are absolutely correct. If it cannot be proved
mathematically
then we have an enigma wrapped up in a mystery paper and we can
declare that
'The Emporer is not wearing clothes!"
Best Regards
Art Unwin KB9MZ.....XG.

remaining definition of "is" omitted....

Hi Cecil,

Well, the problem is then equally shared with your answer isn't it?
That is the irony of such condemnation, your own foundation is built
on the same drifting sand.

Well, I didn't expect any math problems revealed, and there is no
offer of a new physics of transformers emerging to challenge the 19th
& 20th centuries' understandings.

If one adds two and only two waves, one cannot at the same time obtain the sum of the voltages and the sum of the currents without doubling the power output of the transmitters which changes the voltages and currents from what they were initially. The voltage equation doesn't balance because it is impossible to balance the voltage equation with two and only two components. You proved that with your observation.

Let's say we manage to sum the outputs of two 100 watt transmitters into a single load. The power to that load is 200 watts. The sum of the voltages is NOT what appears across the load and the sum of the currents is NOT what appears across the load. If both transmitters are putting out 70.7v at 1.414a and you sum their outputs into a 50 ohm load by network matching, the best you can do is 100 volts at 2 amps or 200 watts. Blood out of a turnip comes to mind.

You cannot take two 100w transmitters, each putting out 70.7v at 1.414a and sum the outputs to get 141.4v at 2.828a. That's getting 400 watts out of two 100 watt transmitters. All I am saying is that Steve left some energy out of his energy equation.

> The transformer
> example he gave is obfuscation unless he can prove that his transformer is
> directly analogous, mathematically, and physically, with a transmission line.

It is analogous in that both are required to satisfy the principle of the conservation of energy. The transformer has multiple primaries and a single secondary. If you cannot perform the same feat with a transformer that you perform with a transmission line, then something is missing. That something is the power involved in the interference pattern which exists in a transmission line but not in a transformer.

> You're right, Richard, both Cecil and Steve eventually
> come up with the same numbers, ...

Ahhhhh, but as you can see from my follow-up posting, Steve lives in a universe where the conservation of energy principle is meaningless and one can obtain more power out of a transformer than one puts in.

Hi Cecil,

I see that you do not dispute Tom's assessment of my observation (nor
my observation). All good and well.

However, you do ascribe an error to Steve, that through symmetrical
results must apply equally to you :-(

Watch the irony, it cuts both ways.

Man, you must live somewhere where it still rains. You couldn't drive nails into the ground here, let alone pieces of coat hangers. Since the grass no longer grows here either, laying radials on top doesn't work too well. You can cut slits into just about anything using a lawn edger with a vertical blade. Cuts a slit about 1/4. These edgers can be rented just about anywhere.

I have had excellent results with IMC THick Wall Galvanized Electrical Conduit. About ten dollars for ten feet of the thick stuff it telescopes together. I started with 1 1/4 then 1 then 3/4 for a thrity footer on my roof (Which gets me to almost 50ft). They fit pretty close to tight by you'll need to insert a nut and bolt or do what I did and drill and tap for a set screw. Supporting a dipole I would use two guys away from the ends. I find masts made this way to be sturdier than the common variety of push up's. Remember to leave the plastic busings in as thy make the telescoping fit better. If you don't want or need to telescope you can simply connect them together with the included couplings. I also use the 1 1/4 " as a mast on my tower. It supported a tribander for the last five years.

> criticism...No flaming intended. MK
Keith,

No. Of course not, you are friendly and you have followed pretty good.
Sometime one strays from the task at hand to answer a question which
can then confuse others who thought they had things corectly.
Let me try it again and you can use your EZNEC which I have not used
and model the following:

A twenty metre length dipole unbroken at its center.
Feeding method should be a delta match I.E. two connection points
about the center which tapers down to to a feed point commonly used to
reduce a high impedance to a low impedance.
Hopefully you followe that as it is pretty standard.
Now place in close proximity say an inch away from the center of the
previous
dipole, a loop antenna which is variable with the use of a capacitor,
usually in the range of 5 to 60 pF when looking at the range 14 to 30
Mhz.,

This is reshaped or squeezed to form an oblong (very inefficient)
with the long side of the oblong parallel to and about the center of
the dipole.(put the oblong on the other side from the delta match to
make things easier)
With the above you have two resonant circuits which are loosly coupled
to each other.
Now to some this would be no sweat but it may be a hurdle to you.
If we move the oblong shaped loop so the long side touches and become
one
common electrical length which provides for one antenna, dipole
shaped, with a parallel cuicuit at it's center. On the other side we
have the delta match connected.
Now we can model it as a single antenna where the object is to radiate
bidirectionally and where the capacitor provides for a constant
impedance at the feed point through out any portion of the range
provided by the now co-joined loop in a similar fashion it would do
separately and away from other radiating members.
So now you must look at the possible variables as follows:
We are striving for a constan impedance around which every thing
revolves
As I said in another posting, to use the range of capacitor given if
you go to the charts it will provide for a common reactance, 250 ohm
seems a good choice
thought you can go higher or lower depending on attributes later
desired from the antenna.
Great..... we have got rid of one variable.
Now we hae two variables left assuming that we have decided on a
common
diameter for all parts of the dipole. (later experience will show
that modification of various diameters can/are useful, but at this
time we are not interested in niceties...keep it simple.
We now have the basics for a program where the only variables are the
overall length of the dipole and also the length of the parallel
circuit or contact point of the quasi loop
So now we can use a computor program which comprises of a sweep thru
the basic frequencies provided by the loop to obtain a common lengths
throu out the
frequency range.
I rely on your useage of computor programing of which I am not an
expert, to come up with the final figures.
Note, when you look at your created current curve for the antenna you
will note
that the loop is ineffective when using for twenty meters and will
provide
for the normal current curve(one current maxima) and a bidirection
radiation pattern.
As you move towards the other end of the range, 10 meters, the current
curve will become mischapened and provide for two points of current
maxima in hase,which in turn supplies collinear gains over a simple
dipole.

At the extreme range the current curve will provide for two full an natural curves, in phase, which supplies the maximum collinear gain availabble for the above antenna arrangement.

8888888888 cap 88888888
LOOP 8 8
8888888888888888888888
1111111111111111111111111111111111111111111111111111111111111111
< coupling length >
DIPOLE

feed point ca be anywhere, for atarters, about the center point

If past experiences are observed the more that is said of this antenna the more it becomes confusing. On another thread the basics that this design revolves around, accepted laws of nature, has come to a screeching halt because one of natures laws has been violated and I am stuck here in first year 101, cannot proceed.Stop and reregister next year.

Hopefully all is now very clear and you can play with your programing to emulate
what the above antenna does in practice over and over with predictable results
that I assume all will turn to over the tradititional as shown by Uda with the traditional yagi.

Have fun Keith, give a shout if you need extra guidance.
And as I have said in private you appear to be the only one to give it a shot on the computor and put your personal beliefs aside.
Great job.
Warmest regards
Art Unwin

Nope it isn't, Richard. The point is there no law of physics that
says the voltage equation must balance. However, there is a law of
physics that says the energy equation must balance. If the choice
is between balancing the voltage equation and balancing the energy
equation, balancing the energy equation wins every time.

Given two primary inputs on a transformer and one secondary output
on the transformer, there is no way to achieve 106.066 volts at
0.707 amps on one input, 35.355 volts at 0.236 amps on the other
input, and have 141.4 volts at 0.943 amps on the output. Clearly,
if the transmission line is capable of such a feat, then something
important has been omitted from the equations. That something is
the energy involved in the interference pattern which contributes
to the forward voltage and current.

On this subject, I think you've hit the real issue here Mark. I have followed the "Fractenna" debate for some time with initially great interest, it's now a much more weary trawl.

Personally, I am now very interested in these E-H antennas. When I saw them I thought "you must be joking", but I try to keep an open mind. However the proponents of this and other "new" technologies seem to feel the need to act like QVC presenters, and attempt to blind us with pseudo-science and marketing babble.

I would love to see some of these guys engage in a more honest debate. Less of the marketing hype, and a bit more REAL FACTS AND FIGURES. These should be reproduceable for verification. I'd be impressed by a headline on the QRZ site saying "Fractenna beats all comers" as a result of his attendance at one of the open antenna comparison days that I believe the ARRL run from time to time. I've a feeling I'll have a long wait.

I am afraid the cynical amongst us will continue to wonder what they have to hide if they continue to hide the REAL science behind a barricade of lawyers and marketing men.

However, I have no doubt that new antenna design await discovery, but babbling on about "quantum radiators" and similar rubbish does nothing to impress or earn my respect from a scientific point of view.

One last point, you mention modelling, I presume by computer. If a "new technology" was to be discovered, it could be a waste of time attempting to model it using software based on "old technology". For example a mathematical model of a steam engine will not tell me much about the prospective power output of my new V8, would a new antenna technology be so radically different - it could be.

Kind regards

Alec Wood M1BNK
Teesside UK

Hi Cecil,

I have no interest in the specifics of the problems you maintain
plague Steve's argument for they plague yours as well by symmetrical
results. Unless, of course, your universe is non-linear. THAT would
be a more interesting topic of discussion.

Here's how to satisfy both the superposition principle and the conservation
of energy principle.

Consider P1 + P2 + P3 + P4 = Ptot

You say there is not an equation that will satisfy

sqrt(P1) + sqrt(P2) + sqrt(P3) + sqrt(P4) = sqrt(Ptot)

I say you are wrong. The square root of a number can be either
positive or negative. There exists a solution to both equations
that allows the voltages to sum to the correct value and the
powers to sum to the correct value.

The reason that the previous equation did not balance when the
square roots were taken is that the voltages that cancel were
left out of the equation.

I have already published the consistent results. The voltage equation is:

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

The power equation is: 75w + 8.33w + 25w + 25w = 133.33w

Both equations balance perfectly and are perfectly consistent with
reality and the laws of physics. Why not adopt them?

Hi Cecil,

Back to boring. I've already demonstrated the principle using your model, and your numbers. I don't think it necessary to repeat this for each twist in the road.

Find a power engineering equation that demonstrates your assertion above, offer a citation, and show your own work this time.

Nope they don't, Richard. I have already published perfectly consistent
results. Perhaps you missed them.

75w + 8.33w + 25w + 25w = 133.33w

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

Both equations balance. No violation of the superposition principle
or the conservation of energy principle. What's wrong with that?

It's pretty obvious, Richard. Take a transformer with those two signals
as the inputs. Try to get 133.33 watts out of a transformer when the
two powers on the inputs total 83.33 watts. Clearly, something else
is happening in the transmission line. That something else is the
energy involved in the interference pattern which doesn't exist
in the transformer.

Slight correction: The above statement applies to transformers. For
transmission lines I should have said that there is no law of physics
that calls for the preservation of voltage.

Hi Cecil,

They must, you two are arguing the opposite sides of the same coin.
If you can point to an error in one, it must exist with the other -
the same math and the same model was used both times.

> They must, you two are arguing the opposite sides of the same coin.

No we are not, Richard. I am arguing a perfectly consistent side
where all the voltages add up to the exact value they should and
all the powers add up to the exact value they should. Steve's
powers don't add up.

2712. Re: Shielded parallel feedlines

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-12 19:46:19 UTC
From: Dave Allen <david_e_allen@agilent.com>
Message-ID: <3D58108A.32E8516A@agilent.com>
Source record: 137053

My (future) solution to this will be a remote tuner at the base of the antenna (under the feedpoint). Best of both worlds - open feeder between tuner and antenna, and coax to bury, etc coming into the shack. And better lightning protection available for coax (none really for open wire). The burying itself is good lighning protection.

I built this J pole antenna and it works quite well the only modification was wear the swr adj screw nut. I fitted into a drilled hole in the pipe cap. It was easier than trying to hold it from below and I was worried about solder getting into the threads.
Up at 20 feet i can few hit a repeaters 20-40 miles away with HT at one watt.

You've challenged me to review conservation of energy, and I did. This
is not simply a quick look at the Antenna Book - I've examined
transmission line, antenna, general electromagnetics, physics, and
systems (radar) texts. The following is a sample of significant
results from some of the heavyweights. I hope you're happy with the
results. To all casual readers who don't want to read all the details,
skip down to the Summary.

A transmission line text
on pp. 137-138 of Transmission Lines and Networks, by Johnson, he
works an example to find the receiving-end voltage, current and power

using a transmission line chart. He simplifies it by saying that "the overall losses are small (alphaL << 1), and so we can use the principle of the conservation of power." ... "Since the losses in the line are negligible, the receiving-end power is equal to the sending-end power."

Also (p. 145): "If the current and impedance at one point are known, the magnitude of the current at another point can be found from the conservation of power"

On p. 14, Johnson presents an example of a battery connected to one end of an infinitely long line. He then presents expressions for the incremental energy, the total stored energy on the line, and the rate at which energy is increasing. "This [rate at which energy is increasing] is, of course, equal to the power continuously supplied by the battery."

I could find no indication in Johnson of a destructive interference pattern resulting in a constructive interference.

Another transmission line text
There is only index listing related to energy in Microwave Transmission by Slater. This one entry is for energy density related to Poynting's vector. There are no index entries for conservation or conservation of energy.

Still another transmission line text
There are no index entries for conservation, conservation of energy, or energy in
Field Theory of Guided Waves by Collin. (There is an entry for energy transport
velocity, but that's a different concern).

Yet another transmission line text
In Transmission Lines and Waveguides by Blake, there are only two index listings related to energy. These entries (p. 3 and p. 4) deal with the difference between the transmission of energy (power) vs the transmission of information (signals).

An antenna text
From p. 10 of Antennas, by Lamont Blake
"One of the fundamental laws of physics is the Law of Conservation of Energy. An
electromagnetic wave represents a flow of energy in the direction of propagation. The rate at which energy flows through a unit area of surface in space (energy per unit time per unit of area) is called the power density of the wave, usually expressed in watts per square meter. The principle of energy conservation can be applied to a

uniform spherical wave in the following terms, with reference to
Figure 1-2. If the source radiates power at a constant rate uniformly
in all directions, the total power flowing through any spherical
surface centered at the source will be uniformly distributed over the
surface and must equal the power radiated."

Translation: Suppose there's an antenna in free space and the input
power to it is 100 watts. Obtain the power density at points on a
sphere a large distance from the antenna. Integrate the product of
power density and surface area over the complete surface of the
sphere. The answer, according to conservation of energy, must be 100
watts. Blake uses an isotrope, but this works for any antenna.

Again, I could find no indication that constructive interference is
caused by a destructive interference pattern.

An electromagnetics text
>From pp. 21-23 and 28-30 of Advanced Engineering Electromagnetics by
Balanis
"within a region V bounded by [enclosed surface] S, the supplied power
is equal
to the power exiting S plus the power dissipated within that region
plus the
rate of change (increase if positive) of the electric and magnetic
energies
stored within that same region."

Translation: the sum of the power lost to heat, appearing as either
electric or
magnetic energy, and flowing across the surface equals the supplied
power. There is nothing about a destructive interference pattern
leading to a constructive interference.

---
physics texts
The physics texts I examined (four) deal with conservation of energy
mostly in the contexts of mechanical systems, thermodynamics,
acoustics, and wave propagation in fluids.

Terman
For those fans of Terman (count me as one of them), both the 1937 and
1947 editions of Radio Engineering have absolutely no index entries
for conservation, conservation of energy, or energy.

Summary
For transmission lines, conservation of energy means that the power
delivered to the load is the same as the power generated by the
source.

For antennas, it means that the total radiated power over the surface of a sphere is the same as the power radiated by the antenna.

For general electromagnetics, the sum of the stored electric and magnetic energies, the power flow out of the bounding surface, and any dissipated power must be equal to the supplied power.

In all the texts reviewed, there is absolutely no indication that a destructive
interference pattern at one point results in a constructive interference somewhere else. If conservation of energy is so extremely important to us engineers, you'd think it would be dealt with in exhausting detail in every text. It isn't.

In the context of your simple problem, the only thing to be said about conservation of energy is that it is not violated - the power dissipated in the load (100 watts) is identical to the power generated by the source. And that's all that can be said.

If you still insist on using conservation of energy to argue your position, maybe you could supply the name of some top-notch reference that we all could read. Otherwise, you haven't made your case, and you're using this principle inappropriately.

73,
Bill N3WK

2718. How far away: HF Dipole and tri-bander vertical?

Newsgroup: rec.radio.amateur.antenna

Source record: 137059

I can put my triband antenna (50/144/440 MFJ-1536 just reduced to $119) 3 ft above the center insulator of my multi-band HF dipole 60 ft from my shack (where it will out of sight = XYL happy), or over my shack (where it will be in the view = XYL unhappy). If I put it near the dipole, will 600 watts of HF de-sense the tribander on RX, assuming I am using a VX-5R or similar?

I suspect it will since a mere 100 watts of CW on HF makes the TV's within 20 ft of the dipole blink. Will things be satisfactory even if the antennas are 60 ft apart? Should I just resign myself to doing HF or VHF but not both at the same time and put the antennas close?

Source record: 137060

I need some advice on the design of a long wire antenna.
I have about 150' length of space to work with. The antenna
must be end fed. I would like to use it primarily for 80-40 meters,
but if it works on other freqs thats okay too. I realize that I will
more than likely need an antenna tuner to match the impedance
of the antenna to 50 ohms coax connector of the transmitter.
Its been a lot of years since I've put up an antenna. Any design
tips, sites with good designs on them etc would be most
helpful.
Thanks

> --

Your example is going to take us right back to the same place we were sometime again. We both agree on the steady state conditions in terms of voltage, current and power. There are multiple forward waves that combine (constructive interference in this case) resulting in a total forward power of 133.33 W. There are multiple rearward waves that combine (destructive interference in this case) resulting in a total rearward wave of 0 W. We only disagree in the physical interpretation of what's happening to cause this.

My interpretation is that the superposition of voltages is sufficient to explain what happens in either direction and that the law of conservation of energy is satisfied because the total net power flowing into the junction equals the total net power flowing out of the junction.

Your interpretation requires me to accept that the energy involved in the destructive interference somehow manages to reverse direction and join the forward traveling energy. There is no physical mechanism that can cause this to happen, so I simply disagree with your interpretation.

Lets accept that we disagree on the physical interpretation of your example and examine my example proposed just recently. In my example the multiple

forward waves (75 W and 8.33 W) superimpose to bring the total forward power to 133.33 W but there is no corresponding destructive interference (energy cancellation) anywhere else in the system. I would like to see how you explain this.

Steve VE9SRB

Bill

I proposed a simple example to Cecil where there are multiple forward waves (75 W and 8.33 W) that combine to result in a total forward wave with a power of 133.33 W. In this example, there is no place in the system where there is a corresponding level of destructive interference as Cecil's Law of Conservation of Energy interpretation would require. I would like to see how he explains this.

The example is very simple.

141.421 V -- 50 ohm source Z -+----150 ohm line 1 WL ----+-50 ohm load

From the initial state to the steady state there is only constructive interference and the total power continues to increase everywhere. There is no destructive interference. The law of conservation of energy still applies in that the total power delivered by the source equals the total power dissipated by the load.

First George I am not upset with your post.If I remember correctly you
sent me a similar one years ago. At that time this group with Tom W8TI
at the fore front
(must not forget Force 12 who had a booklet on the subject) were
lashing at
all manufactures for claiming things that they could not produce or
was misleading.
Also many times, myself included, was shown to be lacking with
computor programs
education where many claims were made in error based on faulty
programing.
Even tho a business man W7ET, wanted to totally finance the operation
in which I would have a controlling interest. I was VERY concerned at
the ethics of such a venture that possibly, I also would be making
clains that were untennable.
I could have rested on 'buyer beware" but that is not how I or my
family thinks who were aware that their money return would be made
quickly if ethics were ignored
I have or had patents that describes the antenna, that describes the
antenna to the PTO's satisfaction. The single claim allowed in no way
reflected what I asked for and I will post a news account of my
struggles where the patent office suggested that it was this or
nothing. That was totally restricted in phrasing such that it was
useless as a future business tool.
What people say I should have done cannot now be done. Frankly you
have no idea
of the many hurdles I had to overcome. It is all in the past now and I
have now abandoned all rights that I may have had. I know I do not
have the RIGHT to ask my peers or possible elmers why the antenna
works or doesn't work, but I had hoped for an explanation, somewhat in
depth as given to SWR meters, conjugate matches e.t.c
Being well into retirement I have no aspirations in life left other
than to get this load off my concience so I can explain to those close

to me how I failed them, nothing more.....no monetary interests left (My family doesn't ask for explanation ofcourse.) You have been informed in a loose sort of way of certain efforts I made in those years and with the news article that will be placed on the net you will realise that efforts that I have already informed you of are miniscule compared to what at present you do know.
Even as monday morning quarter back could I have perceived that what I was to run into. My struggles and the controlling ethics is more that you can see unless you are able to walk in my shoes. But no matter, I am trying to share with all what I have found to be a terrific antenna that provides an advancement over the Uda Yagi array. An antenna that deserves our attention because of the 'leap in the state of the art' which I believe it represents.
It has a patent, readily made with predicted radiation patterns, excepted by the U of I. Yes, I know similar claims have been made before and have failed to materialised,
In my case I believe I have supplied reasonable credentials to worthy an examination by my peers. I will catch hell from all if my antenna does not produce my claims which will follow me for ever, but as a former engineer of many years I truly believe all that I have said and done with this antenna
is true.
Lets all have fun and be happy, this could be the big laugh that we all have been waiting for. Time for all of us to lighten up.
Art Unwin KB9MZ.....XG

Hi Steve,

You might look into the American Red Cross or the Salvation Army. Here in Charlotte NC, each of these groups have a ham radio club associated with them. The charity provides space for a club room and the members provide emergency response communications. If such an arrangement exists in your town, they would be happy to take you up on the offer.

Good Luck,

Bill, W4WNT

Hi Tom,

Considering that a G5RV has a very complex pattern even when hung straight and high, you may not affect it much by doing an "upside down Vee" if the feed point is 20 feet off the ground. You could even do an inverted W which might take less space. You will be using a tuner anyway you set it up.

Good Luck,

Bill, W4WNT

Placing the elements above the boom creates a torque along the boom.

It's generally easier to install an antenna with the elements on the underside, since this is the way gravity pulls on the antenna.

I put the bolt head on the upper side of the boom, and the nut on the lower side (against the elements). Probably doesn't make any practical difference, but it would seem to encourage water to drip from the smaller area.

"---a terrific antenna that provides an advancement over the Uda Yagi array."

Apples and oranges! A delta matched dipole may match a transmission line more handily than a multielement parasitic beam, but the Yagi will likely produce more signal with less noise.

Please be reasonable with us. Give us a comparison of the dipole with the novel matching arrangement versus the same antenna with not so equipped. Thanks.

Best regards, Richard Harrison, KB5WZI

Same thing as they do at 60Hz for power supplies, just at RF instead.
Trivial and obvious. Not pulling your leg - I'm just about ten to fifteen
years ahead of my time.

You know something tells me that a simple random wire strung at an angle to the top of the tree and fed against the frame/body of the mobile home would give a good account of itself. You would need a random wire tuner at the shack end, an L-network or similar, or one of the new computer aided would work fine. It would be a very convenient all band antenna and depending on your ground conductivity might be a very good performer.

Tony

> that we all could read.

An argumentum ad verecundiam, Bill? You are reading that top-notch reference right here. The aliens abducted me, explained all this, and told me to teach it to RF engineers :-) Seriously, we are delving deeper into this subject than has ever been done before. This all started when Steve attempted to prove that Walter Maxwell was mistaken with his "100% re-reflected" statements. Well, Steve succeeded and now must face the consequences of taking such a close look "into the conjugate mirror". Since this is apparently a new theory, I'm going to publish something and submit it for peer review. It would be a lot easier to explain with proper graphics.

You guys remind me of the doctor when I say, "Doctor, it hurts when I do this." The doctor responds, "Well, then don't do that". I am thinking thoughts that apparently have never been thought before. Your advice is to stop thinking and seek advice from experts who also have never thought those thoughts before. No thanks.

I notice that before you were challenged, you had no problem breaking down all the waves into their separate voltage, current, and power components. You discovered where that path leads and are apparently backing off from it. Well, I'm not. Thar's joules in them thar waves. The wave voltage and current are constrained by certain boundary conditions one of which is an absolutely necessary energy foundation under each one. If an electron can be considered independently, there's no reason each wave cannot be considered independently. It's up to an individual to choose to do so or not.

Take a look at the example I made up for Steve and tell us how the 25 watts of previously reflected power makes it to the load when the load is changed without adding to the voltage and current in the forward wave. Can we at least agree that all the generated power that makes it to the load must have joined the forward power in the transmission line? How else can it make it from the source to the load?

If you don't want to think about it, that's your choice. But it is you
who triggered this discussion with your assertion that 75 joules/sec
plus 8.33 joules/sec equals 133.33 joules/sec. You didn't make that
statement in your magazine article, did you?

> Your interpretation requires me to accept that the energy involved in the
> destructive interference somehow manages to reverse direction and join the
> forward traveling energy. There is no physical mechanism that can cause
> this to happen, so I simply disagree with your interpretation.

You have got to be kidding. For that, I can surely find a reference. How
do you think antennas manage to achieve gain? Are you familiar with the
MOM software?

The physical mechanism that causes destructive interference to happen is when
two waves collide such that the two voltages are equal in magnitude and opposite
in phase AND the two currents are equal in magnitude and opposite in phase.
Bill calls it cancellation. Waves can be canceled but the energy in the waves
cannot be canceled. We know it is canceled toward the load. The only other
possible direction for that energy to go is back towards the antenna. It cannot
stand still.

> Lets accept that we disagree on the physical interpretation of your example
> and examine my example proposed just recently. In my example the multiple
> forward waves (75 W and 8.33 W) superimpose to bring the total forward power
> to 133.33 W but there is no corresponding destructive interference (energy
> cancellation) anywhere else in the system. I would like to see how you
> explain this.

I notice you didn't answer my question. How does that 25w of reflected power,
dissipated at the source when the load is 150 ohms, make it to the load when
the load is switched to 50 ohms, without joining the forward voltage and
current? Where is that 25w in your 75w + 8.33w = 133.33w equation? That equation
continues to be ridiculous. Have you explained to the power companies that
83.33 watts equals 133.33 watts and therefore they should lower your power
bill?

I'm going to write an article, complete with graphics, and at least put it
on my web page. I might even talk some magazine into publishing it.

Steve, this example is identical to the other one. All the voltages, currents,
and powers are identical. The only thing that has changed is that, instead of
a Z0-match, we now have a Zg-match. Nothing conceptually new here. The
reflection at the 50/150 junction is a same-cycle reflection but the
reflection mechanics are exactly the same as the earlier example. The '+' sign
marks the location of the Zg-match. The destructive interference takes place
at that point just like it took place at the '+' sign in the other example.

That's not true at all. If your so sure, then describe the initial state conditions, the steady state conditions and the relationships between all forward and reflected voltages, currents and power. As in the other example, there is a 75 W and an 8.33 W forward wave that superimpose to result in a 133.33 W forward wave. However, there is no destructive interference or energy cancellation anywhere else in the system to give the extra energy you require to explain what happens in your example. I would like you to explain what happens here under those conditions.

I got lost a while back, but I've been 'listening' with interest.

This may be overly basic, but then again...can't be too careful.

Make sure that when you multiply volts times amps to get watts that the volts and the amps are both happening in the *same place* along the transmission line.

Alec, you make a very good point regarding computor programs
In my earlier days I tried to model a particular antenna I was playing
with.
The computor gave me 20 odd db gain which I was looking for
naturally!
Unfortunately I was a victim of poor programing and stuck with the
view of garbage in/garbage out. So when I tried to model combination
antenna it again suplied me with answers that I liked and expected,
who wouldn't?
So please understand my reluctance to provide copies of my programing
since a defect in the programing would remove all interest in the
actual antenna.
I am not knocking programing but my early efforts especially with this
particular antenna gave me fits from which I have not as yet
recovered.
Getting older seems to make the chance of making programing errors
more probable
which is my one fear with respect to this antenna even tho it works
just like the results showed.
Cheers and beers

Ed -

I contacted MFJ this morning, and received a couple of very quick responses ()best you not know how that was accomplished)

AS MR. McLaughlin has suggested a current or "new" P.E.'s review of the design may be the best bet, okay here are the details:

When MFJ purchased Hy-Gain from Telex, there was quite a bit of the original documentation and information supplied AND quite a bit that was missing or lost through the years at Hy-Gain,
MFJ actually had to go to the advertising companies used by Hy-Gain through the years to recover the original photographs, pictures and text for the MFJ catalog -- that process alone took over one year.

If the Hy-Gain staff has advised that they don't have the original engineering data that Ed requested, it may well be that the originals documents have been lost.

Have Mr. Juge contact Randy Nash, Hy-Gain Antenna Production Manager. Randy was responsible for the reintroduction and reproduction of the Hy-Tower product. He will supply what information he has available for Mr. Juge's zoning board. 1-800-973-6572.

MFJ / Hy-Gain Antennas

Best luck

I have proved my point, Richard. You just haven't accepted it. I'll write an article and see what happens. What is wrong with the following equations?

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

75w + 8.33w + 25w + 25w = 133.33w

Voltages sum to the proper value and power sums to the proper value. What more do you want?

It appears all you have changed from the other example is to remove a piece
of coax that had an SWR of 1:1. That's no change at all, Steve. I am amazed
that you do not know that. The only change is that the generated power
reaches the 50/150 junction a little faster. Steady state conditions are
identical because nothing has changed.

2744. Electrostatic and magnetic fields

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-13 01:29:16 UTC
From: CW <clinton.magers@attbi.com>
Message-ID: <MhZ59.96291$sA3.24374@rwcrnsc52.ops.asp.att.net>
Source record: 136986

I have been taking an electronics course. One of the classes was a prep course to take the CET exam. We were using a new book and found numerous mistakes. One of the questions asked in the review section was what was the phase relationship of the electrostatic and electromagnetic fields in a circuit. The book said they were in phase but didn't elaborate. My first instinct was that they would be 90 degrees out from one another but now I am not sure. The class discussion was inconclusive. I am sure a lot of you will find this rather basic but that's why I'm asking here.
Help please.

That's wave cancellation. We all agree on this point.

>Waves can be canceled but the energy in the waves
> cannot be canceled. We know it is canceled toward the load. The only other
> possible direction for that energy to go is back towards the antenna. It
cannot
> stand still.
>

I don't think it stands still at all. I think that the rearward traveling energy is there all the time and that all of the energy components traveling in the rearward direction continue to maintain a steady state equilibrium of "cancellation". The time continuous forward source wave arriving at the junction must continuously develop a rearward traveling component of energy because of the physical boundary it continues to encounter at the junction. The time continuous reflected wave must continuously transmit and reflect some level of energy because of the physical boundary it encounters at the junction. These waves maintain a continuous and ongoing state of interaction and superposition at the physical junction. In the rearward direction, the energy in the rearward waves continuously cancels to a net wave of 0 power. This is an ongoing continuous process that maintains an equilibrium that we call the steady state. At any instant in time, the forward wave arriving at the junction can be broken into its transmitted and reflected components. The reflected wave arriving at the junction can be broken down into its transmitted and reflected components.

I don't think we need to go your extra step and state that the rearward energy reverses direction. Your interpretation of energy reversal would require us to accept that the forward source wave no longer develops a reflected component of energy because of the cancellation event that occurs at the junction. There are two major problems with your interpretation.

First, this defies the physical boundary conditions at the junction. Second, the energy can't be going in two directions at the same instant in time. It can't travel in the rearward direction (as required by the physical boundary condition) and the forward direction (as required by your interpretation) at the exact same time. (Note that for the energy components to cancel in the rearward direction, they must be traveling in the rearward direction.)

This may all be a matter of semantics but that's my interpretation.

So, please find and site a your technical reference, other than "Reflections", that specifically states that the energy involved in a destructive interference event in a transmission line must reverse direction and join the forward energy in the line. Also, please site a reference that specifically states that multiple forward powers traveling in a transmission obey superposition principles, such that Ptotal forward = Pforward 1 + Pforward 2.

>
> I notice you didn't answer my question.

I've answered it several times. You don't understand my answer or you simply won't accept that I answered it unless I agree with you. I also note that you will not examine the simple example I posed.

For any independent wave within a transmission line, that is always the case. The transmission line forces certain boundary conditions on a wave. Voltage and current for an independent wave are always in phase or 180 degrees out of phase depending on direction of energy flow. Thus, the cosine of the angle between them is always unity. Thus, V*I is the joules/second associated with that particular wave and that's all the enegy associated with that wave. V/I is the characteristic impedance of the transmission line. Bill performed all the same calculations that I did and came up with wave components identical to mine. From that point, the rest of the story becomes clear, at least to me. The only objections have been, "We RF gurus don't allow ourselves to think such thoughts" and "You shouldn't be thinking thoughts that nobody has thought before", i.e. "Show us some references".

I wonder how Einstein responded when someone asked him for references on the theory of relativity?

Its a very significant change. You would know that if you examinee all the
details of the traveling waves.

>I am amazed
> that you do not know that. The only change is that the generated power

The steady state is identical but what happens to get there is entirely
different and illustrates that your interpretation is incorrect.

Why are you afraid to examine the details of this simple example.

>Help please.

Hi OM,

They can be in any phase, but at your level of instruction the choices
are generally 0ï¿½ and 180ï¿½ with angles in between left for advanced
study. Those topics generally include inductors and capacitors.

The 90ï¿½ that is so impressed upon you is from our discussion of
propagating fields (not the fields you are studying by the way) being
orthogonal to each other. Otherwise, a specific 90ï¿½ phase in
electronics is exceedingly rare. In your course work, you are far
more likely to encounter 45ï¿½ phase relationships because it is also
the -3dB point for a passive circuit which occurs at a frequency of
1/RC.

In your lab work, make every effort to garner a scope and two signal
generators to produce lissajous patterns. This simple method is also
one of the more accurate ones available at the bench for measuring
phase. Grab hold of a couple of L-C-R substitution boxes and you have
the complete lab for studying phase.

Here is a mnemonic to aid you for those phase characteristics
ELI the ICEman
E phase for L circuits is ahead of I phase;
I phase for C circuits is ahead of E phase.
E and I are in phase for R circuits.

> cheers, CAM http://www.qsl.net/w5dxp

Since it appears that you would prefer to ignore this simple example, I'll explain it to you.

Example:

141.421 V -- 50 ohm source Z -+----150 ohm line 1 WL ----+-50 ohm load

In the initial state, before any reflections exist on the line, the 141.421 V source voltage is divided between the 50 ohm source impedance and the 150 ohm line.

The initial forward voltage in the 50 ohm source impedance is 35.36 V. The initial forward power dissipation in the 50 ohm source impedance is 25 W (35.36^2/50). The initial forward voltage in the 150 ohm line is 106.07 V. The initial forward power in the 150 ohm line is 75 W (106.07^2/150).

Now lets jump to the steady state and examine the reflected and re-reflected voltage at the source and apply superposition to determine the total voltages and powers everywhere in the system.

The steady state reflected voltage arriving at the source is -70.71 V. The steady state reflected power arriving at the source is 33.33 W (70.71^2/150). The steady state re-reflected voltage at the source is +35.36 V. The steady state re-reflected power at the source is 8.33 W (35.36^2/150).

The total steady state forward voltage in the 150 ohm line is given by the vector sum of the initial forward voltage (106.07 V) and the total steady state re-reflected voltage (35.36 V). The total forward voltage is 141.42 V and the total forward power is 133.33 W (141.42^2/150).

Now at this point, your interpretation of the law of conservation of energy would require that there be some point of energy cancellation to create the 50 W of power needed to satisfy your power equation of 75 W (initial forward wave) + 8.33 W (re-reflected wave) + (50W of energy cancellation) = 133.33

W.

Where does this 50 W of power come from? Is there an energy cancellation event in the rearward direction at the source? Remember that the initial power dissipation in the source is 25 W. Should the power dissipation in the source now decrease to -25 W?

At the source, there is a rearward voltage delivered to the source impedance that is equal to the sum of the reflected voltage (-70.71 V) voltage and the re-reflected voltage (35.36 V). The total rearward voltage delivered to the source impedance is -35.36 V. Since this voltage is traveling in the rearward direction, the total voltage in the source impedance is equal to the forward voltage minus the rearward voltage. The total voltage developed across the source impedance is equal to 35.36 V - (-35.36 V) = 70.71 V. {ignore the rounding errors} The total steady state power dissipation in the source impedance increase from 25 W to 100 W. There is no energy reduction or cancellation.

While the superposition of forward voltages results in a forward power of 133.33 W, there is no corresponding cancellation of energy event that your interpretation of the law of conservation of energy requires - your extra 50 W of power. It does not exist in this example. In this simple example, the power in the source increase from the initial state, the forward power increases from the initial state and the power in the load increases from the initial state. Yet, the law of conservation of energy is satisfied: The total power delivered to the line (100 W) is dissipated in the load (100 W).

I have been A/B'ing a 60 foot high inverted vee (120 degree apex)
on 20 meters with a widely separated ground mounted
half wave vertical. I've often seen the vertical beat the vee
by 3 to 6 dB and vice versa. Sometimes, they are the same.
Probably depends on the optimum propagation angle at the time.

According to NEC, the vee should beat the dipole at any angle
over any ground (except a couple of degrees over sea water),
and beat it by a significant amount.

I suspect NEC overestimates the gain vee and underestimates the
gain of the vertical (both must be off, you can't explain
the discrepancy only in terms of the vertical being off, AFAIK).

I would be careful about making any assumptions about NEC's
analysis of ground effects. Always A/B real antennas to check.
If necessary, temporarily install switching relays.

> "cancellation".

There are NO energy components traveling in the rearward direction when
the SWR is 1:1. You are back to your phantom wave theory. That's what
happens when you try to violate the conservation of energy principle.
You are forced to come up with supernatural phantom waves that cannot be
detected accompanied by supernatural phantom energy that cannot be detected.

> The time continuous forward source wave arriving at the
> junction must continuously develop a rearward traveling component of energy
> because of the physical boundary it continues to encounter at the junction.

Yes, and for a Z0-match to exist, it must be canceled by a complimentary
wave component from the reflected power that is not re-reflected that flows
through the 150/50 ohm junction in our example. That cancellation is continuous
destructive interference. There is no rearward moving energy on the feedline
with an SWR of 1:1. It cannot be measured. It is not there. There is no other
place for the constructive interference energy to go except back toward the load.

> The time continuous reflected wave must continuously transmit and reflect
> some level of energy because of the physical boundary it encounters at the
> junction. These waves maintain a continuous and ongoing state of
> interaction and superposition at the physical junction. In the rearward
> direction, the energy in the rearward waves continuously cancels to a net
> wave of 0 power.

Exactly, 0 joules/sec equals 0 joules. That canceled (50 joules/sec) energy has
to go somewhere. There is nowhere else for it to go except back toward the load.

> This is an ongoing continuous process that maintains an
> equilibrium that we call the steady state. At any instant in time, the
> forward wave arriving at the junction can be broken into its transmitted and
> reflected components. The reflected wave arriving at the junction can be
> broken down into its transmitted and reflected components.

Bill kindly broke everything down into components. There were eight of
them. Have you read the exchange between Bill and me?

> I don't think we need to go your extra step and state that the rearward
> energy reverses direction.

Of course not because then Walter Maxwell would be essentially correct and
we all know you will never admit that. The conservation of energy principle
tells us that the energy in the canceled waves has to go somewhere since
it cannot disappear from the universe. We know it is not going rearward
toward the load because we cannot measure it. We know it is not standing
still because the Z0-match would explode. So Steve, can you figure out what
only other direction is left? Hint: It's the process of elimination. :-)

> Your interpretation of energy reversal would
> require us to accept that the forward source wave no longer develops a
> reflected component of energy because of the cancellation event that occurs
> at the junction.

That's not true, Steve. The cancellation is a *continuous* process
just like any other superposition of waves. The forward source continuously
develops a reflected component that is interfered with by the continuous
supply of a complimentary wave reflected from the load and not re-reflected
at the boundary. In our example, the power reflected from the load is 33.33
watts. The power that is re-reflected at the 150/50 boundary is 8.33 watts.
That 25 watts that makes it through the 150/50 boundary continuously interferes
with the 25 watts that is reflected from the 50/150 boundary. The phases of
the voltages are opposite and the phases of the currents are opposite. That's
why they cancel and they cancel continuously in a superposed wave pattern.
Voltages can cancel. Currents can cancel. Joules/second cannot cancel.

> There are two major problems with your interpretation.
> First, this defies the physical boundary conditions at the junction.

You have been saying false things about what I am proposing. I assume they
are honest mistakes but it indicates you don't understand what I am saying.

> Second, the energy can't be going in two directions at the same instant in
> time.

Get real, Steve. Does light that bounces off a mirror go in two directions
at the same time? The cancellation happens in continuous time. It is a continuous
process just as bouncing a flashlight beam off a mirror is a continuous process.
Some photons are flowing in one direction while other photons are flowing in
the opposite direction.

> It can't travel in the rearward direction (as required by the
> physical boundary condition) and the forward direction (as required by your
> interpretation) at the exact same time.

It is NOT traveling in the rearward direction and the forward direction at
the same time! THERE IS NO ENERGY TRAVELING IN THE REARWARD DIRECTION IN A
FEEDLINE WITH AN SWR = 1:1. None can be measured. It is not there. Your appeal
to some supernatural phantom waves just won't do. But that is exactly the
position that your premises and logic have brought you to. Next you will
be saying it is that way because God wants it that way. :-)

> (Note that for the energy
> components to cancel in the rearward direction, they must be traveling in
> the rearward direction.)

While they are being superposed into cancellation, they are traveling in the
rearward direction for an infinitesimal distance, i.e. a distance that approaches
zero in the limit. At any measurable distance away from the Z0-match, there is
NO REARWARD ENERGY FLOW! If there were a rearward energy flow, we could measure
it and the SWR would not be 1:1. Please realize that everything is happening
at an infinitesimally small point at the Z0-match. One micron from the Z0-match
back toward the source, there is ZERO rearward traveling energy.

> So, please find and site a your technical reference, other than
> "Reflections", that specifically states that the energy involved in a
> destructive interference event in a transmission line must reverse direction
> and join the forward energy in the line.

Seems to me, I should be able to find a reference that says that. It may,
however, be an optics reference but valid for any EM waves.

> Also, please site a reference that
> specifically states that multiple forward powers traveling in a transmission
> obey superposition principles, such that Ptotal forward = Pforward 1 +
> Pforward 2.

The powers don't obey superposition principles, Steve. Voltage and current
obey superposition principles. Powers (of the nature of joules/second) obey
the conservation of energy principle. I have said this until I am blue in
the face. Why aren't you listening?

The superposed voltages in our example are:

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

The superposed currents in our example are:

0.707a + 0.236a + 0.707a - 0.707a = 0.943a

The last two terms in the sum are the two interference voltages.

The conservation of energy equations are:

106.066v^2/150 + 35.355v^2/150 + 35.355v^2/50 +(-35.355v^2)/50 = 141.4v^2/150

0.707a^2*150 + 0.236a^2*150 + 0.707a^2*50 +(-0.707a^2)*50 = 0.943a^2*150

75 joules/sec + 8.33 joules/sec + 25 joules/sec + 25 joules/sec = 133.3 joules/sec

Voltages are consistent and obey the superposition principle.
Energy is consistent and obeys the conservation of energy principle.

What is wrong with an explanation that is consistent with all the laws
of physics?

> I've answered (your question) several times.

Nope, you've mealy-mouthed around it several times. How do you get 25 joules/sec
from the source to the load without it becoming part of the forward wave? We
know it gets there. How does it get there? Supernatural Phantom Waves? It's
not there in your 75w + 8.33w = 133.33w equation. Where is it?

> I also note that you will not examine the simple example I posed.

I examined it, Steve. It is identical to the other example except the Z0-match
has been replaced by a Zg-match. There's nothing new to discuss. Consider that
all the voltages, currents, and powers are identical to the other example.

I have examined them, Steve. I don't see any difference between a source with a 50 ohm source impedance and a source with a circulator load of 50 ohms that dissipates all the reflected power. Please explain the difference between encountering a 50 ohm resistor as the source impedance and encountering a 50 ohm resistor as a circulator load. How does the reflected power know the difference between those two 50 ohm resistors? Are you aware that reflection wave mechanics works perfectly well without a transmission line?

> (35.36^2/150).

The fact that you assert that 8.33w is re-reflected means it must be reflected
from a 150 ohm to 50 ohm impedance transition. So you are admitting that a
Zg-match exists at that point. That point acts identically to the Z0-match
point in the earlier example. You cannot have it both ways, Steve. Either
the Zg-match point exists or it doesn't. If it does, it acts exactly like
the earlier Z0-match point. If it doesn't exist, there won't be 8.33 watts
re-reflected. So please make up your mind.

> The total steady state forward voltage in the 150 ohm line is given by the

> event in the rearward direction at the source? Remember that the initial
> power dissipation in the source is 25 W. Should the power dissipation in
> the source now decrease to -25 W?

It is the same as before, Steve. Of the 33.33 watts of reflected power, 25 watts makes it through the Zg-match point, i.e. the point where the impedance transitions from Z0=150 ohms to Zg=50 ohms, you know - the point where your 8.33 watts re-reflected occurs. It wouldn't be re-reflected if the Zg-match transition point didn't exist, now would it? The reflected power is 33.33 watts. The re-reflected power is 8.33 watts. That leaves the same 25 watts that we encountered in the first example.

Of the 100 watts of forward power from the generator, 25 watts is reflected at the Zg-match point, i.e. the point where the impedance transitions from Zg=50 ohms to Z0=150 ohms. If, as you say, the 150/50 transition point causes 8.33 watts of re-reflections, then it has to be causing 25w of reflections from the 100w of source power going the other direction. You cannot have re-reflections happening in one direction and no reflections in the other. So there's our other 25 watts. The voltage and power equations are identical to the other example, just as I said they were.

Like I said, nothing has changed. Reflection wave mechanics works even when there is no transmission line.

> At the source, there is a rearward voltage delivered to the source impedance

> {ignore the rounding errors} The total steady state power dissipation in
> the source impedance increase from 25 W to 100 W. There is no energy
> reduction or cancellation.

You are allowing the 150/50 transition point to exist in part of your discussion and then disappear in the other part of your discussion. Please make up your mind. Does the 50/150 transition point exist? If it does, it behaves identically to the Z0-match point in the earlier example. If it doesn't exist, you are going to have to give up the 8.33 watts of re-reflected power. Which will it be?

> While the superposition of forward voltages results in a forward power of
> 133.33 W, there is no corresponding cancellation of energy event that your
> interpretation of the law of conservation of energy requires - your extra 50
> W of power. It does not exist in this example.

Of course it does, Steve. It exists at the Zg-match point. That the Zg-match point causes 8.33 watts of re-reflection proves that the 50/150 transition point exists and cancellation is taking place at that point. You simply cannot have it both ways. Either the Zg-match point exists as a 50 ohm to 150 ohm transition or it doesn't. If it does exist, it acts exactly like the Z0-match point in the earlier example. If it does not exist, you cannot have 8.33 watts of re-reflection occurring. Please make up your mind.

Uh oh... does that mean that if I walk around (or duck under) to the other side of a transmission line and look at it from the other side (thereby effectively reversing the direction of energy flow), that the relative phases of the voltages and currents will change ?

> I wonder how Einstein responded when someone
> asked him for references on the theory of relativity?

Well, he didn't post his theories on an Internet newsgroup.

If the Internet had been invented before the wheel, then the wheel would have never made it past the newsgroup skeptics. We would all be walking...

Thanks for all your comments, Mark. It looks like the problem is the capacitor. My radiator is 112", which is what CC indicated for 50.0 mHz and 4-1/4" of RG-8/U for the capacitor, again, right out of the CC manual. I'll start over again with the long stub, and trim it up a bit at a time and se how close to CC's length I end up.

I made my rings out of aluminum tubing (and that was really fun bending too <grin>) to reduce dissimilar metal corrosion as much as possible.

Thanks again for all your input.

Richard Harrison wrote:
>No observant knowledgeable person would argue that the Bird wattmeter
>does not work.

The Bird wattmeter is very poor evidence for anybody's argument, because it does not truly measure watts.

The sensor in the Bird does not sense power. It generates two RF voltages - one proportional to the RF voltage on the line, and one proportional to the RF current - which are added or subtracted. There is no multiplication of voltage and current, so there's no power detection here..

When the sensor is rotated in the 'forward' direction, the total RF voltage is proportional to the vector *sum* of the voltage and the current in the line. Rotated to the 'reverse' direction, the current-signal is reversed in phase but the voltage is not, so the sensor generates the vector *difference*. With a matched load, the sensor is designed so that these quantities are equal and opposite in the reverse direction, so the difference is zero.

The sensor also contains a diode detector, which simply detects the net RF voltage (sum or difference) presented to it. What the Bird finally measures is microamperes in the meter movement.

The conversion from microamperes to indicated RF power takes place literally on the scale of the meter - no electronics involved at all. That "power" calibration is only valid for a 50 ohm load [1].

Any other so-called RF "wattmeter" that depends on sensing voltages and currents on the line is the same - it isn't a true wattmeter because it doesn't truly sense power. On the contrary, its power calibration depends *totally* upon the theory that you're trying to discuss here.... so if you try to call the Bird wattmeter as a 'witness', you're into a circular argument.

[1] With a mismatched load, both the forward and reverse power indications are invalid. However, such meters have the peculiar property that the difference between the indicated forward and reverse powers is equal to the power delivered to the load, regardless of the actual load impedance. But this is a peculiarity of the meter - it still doesn't mean that it senses true power.

Hello,

I am new here and hope someone can help. I will hopefully be getting my 9V1 license before the end of the year (a full license for the HF bands). I am not familiar with amateur antenna systems in particular although I do understand general antenna theory. The problem in Singapore is that most of us live in apartments, myself included. I am on the 2nd floor of a 4-floor block. I have considered end-fed longwires via an ATU but I do not think the condominium management would approve . What they are really after is something out of sight. The roof may be an option. It is flat. I could mount a vertical with ground-plane radials no problem. The management would probably balk at anything higher than 15 feet, however.
An ATU could be mounted a the base of the antenna and weatherproofed. With such a small space available to me, what do you suggest as an off-the shelf antenna ? To make things worse, the roof access would be closed off to me after installation so I could not use any manual traps or such like. I would like to operate on all hf bands but I do realise that 80m may be impossible.
Looking forward to any advice.

Making good comparative measurements isn't easy.

When doing A/B comparisons, *always* make the measurements when receiving. Don't rely on reports from other stations. Make many measurements to average out ionospheric QSB. Especially when comparing vertical and horizontal antennas, take many measurements over a period of time. The received signal polarization can rotate, causing one antenna to be 20 dB or more better than the other at some times, and the other antenna 20 dB or more better at others. This shift can have a period from seconds to many minutes.

If you want quantitative measurements, use a step attenuator when making the measurements or calibrate your S meter on the same band and under the same RF gain, etc., settings with a step attenuator. Don't count on the number of dB per S unit to be constant over the scale, or for there to be a particular number of dB per S unit.

Vertical antennas are much more sensitive to ground conductivity than horizontal antennas (except at high angles), so poor estimations of ground conductivity (ofthen the best you can do) will affect modeling results with verticals more with horizontal antennas.

When comparing antennas with different elevation patterns, the difference between the two depends on the arrival angle of the signal. This can sometimes be estimated with a program like W6ELPROP, but sometimes multiple modes are possible, making it difficult to determine the arrival angle.

Ok, If I read all this right, you are using only one dipole, and one
loop. In that case, I already modeled it correctly the first time.
I've been feeding ity at the center of the dipole. I just wanted to
clear this up , as your ZZ1 antenna appeared to use two dipole
elements. I'll try to double check this, but I think I did it right
the first time. MK

Although trained as an engineer, I am a relative newbie to RF. I found it interesting that the only practical ways we have of generating RF energy is to course alternating current through a wire path (excepting also electric spark). This seems very limited. Light was for thousands of years generated only by burning or heating something, then heating a wire electrically, then applying a potential to some gases, then by chemical reaction, then via soilid-state device. Perhaps a similar future awaits RF and other parts of the EM spectrum. Who is to say we won't find a way to excite matter so that it releases controllable RF energy? Then antennas would look like light fixtures.

There is no NET energy traveling in the rearward direction. We cannot measure the individual energy components. All we can measure is the total net wave component.

Its like a mutlipath fade where different waves meet and combine to a NET energy of 0 at a single point in space. Just because we can't measure the individual wave components does not mean that they no longer exist or that they are not still there effecting the cancellation. The fact that the energy cancels at the multipath fade point does not mean it has to reverse direction, travel or jump through space to somewhere else to combine with other traveling energy components. If it did, the energy in the individual waves would be lost and the waves would not travel past the point where the multipath fade occurs - this would truly violate the law of conservation of energy. For your interpretation of energy conservation to work it must be valid under every imaginable situation - it is not.

Cecil, this has been fun but I'm going to leave the discussion because we have now reached the endless circulating loop. Take care.

Cecil, the rearward voltage (energy) delivered to the source impedance combines with the forward voltage (energy) in the source impedance. The total power (energy) is dissipated there. There simply is no reversal of energy to join with the forward wave.

As I said in the other thread, this has been fun but we have now reached the endless loop of going back and forth, so I'm going to leave the discussion.

Take care.

Assume a dipole, coax and generator in free space,
with no electrical connection to any exernal object.

The generator sends an "electron" current through
the center wire into the right hand side of the
dipole.

Because no electrons leave the wire (true!), the rms electron current arriving at the shield from the left side of the dipole *must* be exactly equal to the rms current that goes into the right side of the dipole.

Because of the requirement that the magnetic field due to the center-wire current and the magnetic field created by the return current on the *inside* surface must exactly cancel each other at the inner surface, the resulting conclusion is that *all* of the electron current from the left side must flow on the inner surface, and none of it flows on the outside surface, regardless of the impedance along the outside surface.

This verifies the claim that all of the current on the outer surface is due to electromagnetic induction, provided that there is no electron current leakage path. Such a path would *contribute* to a common mode leakage electron current.

Note also that Kirchhoff is not violated, but that electromagnetic interactions determine the paths of current. This is slightly different from the conventional lumped circuit.

It is also interesting to consider the mag field cancellation on the inner surface of the shield. In order to achieve cancellation, the two mag fields must be exactly opposite in direction and exactly equal in amplitude at every cross section location. We can see that we cannot depend on the complete path through the coax center wire to the dipole wires and the shield to achieve this cancellation. The probability of this occurring is essentially *zero*.

Instead, the cancellation occurs at each and every cross section. Each tiny segment of coax is a network of series L (both wire and shield), shunt C and mag fields. This tiny network performs, in a complicated way, the desired cancellation at the inner surface. In other words, the coax forces the center current and the return current to be exactly in opposite directions and equal amplitudes at each location. This cancellation occurs on an instantaneous basis.

This does not mean that the voltage across, and the current through, must be in phase (for example if the load impedance is complex). The tiny

network does whatever is necessary to assure the cancellation.

And because of the cancellation, no ac voltage drop occurs along the length of the shield, despite the value of the shield inductance per unit length, which is usually about 25 percent of the center wire value (not zero!).

I'm afraid I'm even more confused now after looking at your patent.
#1, I get no pictures at all, when I try to d/l them. I don't know if
my firewall is blocking them or what. I killed my firewall, and still
didn't get any images.
But in reading the text, it totally contradicts what I was asking you
, and what you state about the number of dipole elements. I asked you
yesterday if the antenna used more than one dipole element. Fairly
simple question really. But you gave me about 87 miles of text, that
after digesting I came to the conclusion that yes, you are only using
one element. So I came to the conclusion I modeled it correctly the
first time. "Actually would have been the 2nd time, as you veto'd the
first." So now I go to the text on the patent page, and what do I see?

"from patent page"
*** BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a variable capacitance antenna having three dipole
elements.

FIG. 2 shows a cross section of the support boom of a variable
capacitance antenna detailing the structure of the variable capacitor
portion and the remote tuning portion.

FIG. 3 shows a rack and pinion movement for the remote tuning portion
of a variable capacitance antenna.

FIG. 4 shows a variable capacitor portion for use with two elements.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. 1 shows an embodiment of the variable capacitance antenna having
three dipole elements. The director element 1, driver element 2, and
reflector element 3 are shown mounted on a common support boom 4. The
variable capacitance antenna requires at least one driver element 2,
however, there can be any number of directors including zero. In a
preferred embodiment, the variable capacitance antenna contains one
director element 1 and one reflector element 3, however, reflector

elements may also be any number including zero.

**** unquote..

Here , you talk of three dipole elements???? Multi elements????
Can you see the contradiction between this antenna and what you are posting here as a description?

I about give up. Until I can get an EXACT picture of the antenna, there is no way I can make any kind of lucid comment on it. Your description you gave me to model does not match this patented antenna. I'm getting almost as confused as you seem to be. Also, you have some other text in that patent that I don't quite agree with. IE: that a trapped dipole is a variation of a yagi, and is limited to three bands. I don't agree with either one of those statements as far as a single trapped dipole.

You claim you can steer a single dipole element by adjusting the cap on the matching device. It's plain to see from modeling, that this is just plain untrue. I can change the value of the cap and it has no effect on the pattern. Only the match.
But yes, if you use TWO parallel dipole elements, each with a cap/loop matching device, it's possible to steer the antenna. Nothing really new there. Whether it's better than using other methods to change phase, I'm not sure. I kind of doubt it. I've seen people using parallel dipoles and "L/C" phasing boxes for years. It seems to work pretty well. Myself, when I did it, I changed the feedlines to change phase. IE: adding lengths to one side of two equal lengths lines, etc. Nothing fancy, but worked ok. Is this what you mean basically? From your patent, it would seem so. Please unconfuse us in a simple "not too many words" manner please. I wish I could d/l the images from the patent site...That would help greatly. Maybe it would help if you could draw an exact picture of the complete antenna, and scanned it and post to the ng. You could put it on your server and post a link. I'm afaid I'm getting more confused by the day. MK

> measure the individual energy components. All we can measure is the total
> net wave component.

Steve, there is no NET energy traveling in the rearward direction because ALL the energy in that direction has been superposed to zero. If there were components of energy flowing rearward toward the source, those energy components would cause losses in the wire. We know there are no losses in the wire from any rearward flowing energy. Therefore, rearward flowing energy has ceased to exist in that portion of the system. It has been canceled by destructive interference. Since energy cannot be destroyed, it has to take the only other possible direction back toward the load through constructive interference. The confining of EM fields to the interior of a coaxial line leaves only two possibilities for the direction of energy flow. If it exists as RF energy and it is not flowing toward the source, then it is flowing toward the load. There's no other possibility. The absence of energy flowing rearward toward the source dictates that all energy at that point is flowing toward the load.

> Its like a mutlipath fade where different waves meet and combine to a NET
> energy of 0 at a single point in space.

Nope it isn't, Steve. In the case of free space, destructive interference can occur anywhere in the fields and constructive interference occur anywhere else. But in a transmission line, the fields are confined to essentially a one-dimensional world. The fields are confined to the transmission line and field components do not extend from the source to the load. Field components are forced by the laws of physics to travel from the source to the load. Since the fields are confined to such a small area, any energy canceled by destructive interference must reappear close by in the transmission line as constructive interference. The physical distance between the destructive interference and the constructive interference is limited by the physical extent of the fields confined to the coax which is a pretty short distance. In the examples given, you cannot sneak energy from the source past the transmission line to the load without it traveling in the transmission line. Nice try but that is simply Hocus-Pocus Electromagnetics.

> Just because we can't measure the
> individual wave components does not mean that they no longer exist or that
> they are not still there effecting the cancellation.

That's an absolute Old Wives' Tale. We know all the energy makes it to load in a lossless system. That energy cannot exist in two places at once. It's either flowing rearward OR it's making it to the load. The same energy cannot be both flowing rearward and forward at the same time. If it is flowing forward, it is not continuing to flow rearward. What is it about "destructive" that you don't understand?

> The fact that the
> energy cancels at the multipath fade point does not mean it has to reverse
> direction, travel or jump through space to somewhere else to combine with
> other traveling energy components.

It travels, it doesn't jump. Your approach has the energy magically jumping from the source to the load bypassing the transmission line. That is simply impossible, Steve. You are going to need assistance from a supernatural RF God to pull that one off.

Any time energy is canceled, it must instantaneously reappear to keep from violating the conservation of energy principle. You say the energy is canceled but it doesn't reappear. That's a clear violation of the conservation of energy principle.

When the fields from an antenna are canceled at a point, they are reinforced at another point sometimes quite a distance away. The reason this can happen with antennas is that the fields are unconfined. They can appear anywhere in free space. The same thing cannot happen with a transmission line where the fields are confined to the interior of the coax and there are no fields outside the (perfect) coax.

> If it did, the energy in the individual
> waves would be lost and the waves would not travel past the point where the
> multipath fade occurs - this would truly violate the law of conservation of
> energy. For your interpretation of energy conservation to work it must be
> valid under every imaginable situation - it is not.

The difference is that in free space, the EM fields are not confined. In a transmission line, the EM fields are confined to the transmission line. In coax, the EM fields are confined between outer layer of the inner conductor and the inner layer of the braid. This puts EM fields in coax in essentially a one-dimensional world. The energy in the coax can only move in two and only two directions. The energy in EM fields in free space are free to move anywhere in free space. In that respect, antenna fields and transmission line fields are quite different.

An antenna field can extend for any distance. A transmission line field confined inside RG8x can extend only approximately the distance between the inner conductor and outer conductor. The distance between the destructive interference and the constructive interference is rather limited inside coax. It certainly does NOT extend from the source to the load as your explanations would have them do.

> Cecil, this has been fun but I'm going to leave the discussion because we
> have now reached the endless circulating loop. Take care.

I have come up with voltage equations that satisfy the superposition principle. I have come up with energy equations that satisfy the conservation of energy principle. You haven't. It seems that our only point of disagreement is whether the energy from destructive interference in a transmission line changes direction and becomes constructive interference in that new direction. I think I can prove my assertion but it will take a trip to the Texas A&M library.

I had the same situation in Spain with miltary housing. BUT, I
presented them with the HF6V and they approved it even though it was
taller. Give it a whirl, I worked the world with it

http://www.bencher.com/hf6vx.html

At 19ft this is a bit smaller, but I cannot atest to the performance.

http://www.cushcraft.com/amateur/details.asp?catid=69

Hygain has the 12AVQ that is 13ft tall but is only 20/15/10
their 14AVQ is 10-40 and is 18ft tall

http://www.hy-gain.com/hy-gain/products.php?catid=4

Good luck and hope to work you soon

Scotty N7HJ

There is no rearward energy delivered to the source impedance during steady
state. It is canceled at the same point at which your 8.33 watts of re-reflections
occur. The same discontinuity that causes the 8.33 watts of re-reflections,
causes cancellation of the rearward wave. You simply cannot have it both
ways. If there exists 6.33 watts of re-reflection, then there exists a
150/50 discontinuity which causes cancellation of the rearward traveling
energy. That 150/50 discontinuity is not some RF diode existing in only
one direction. Or do RF diodes exist in your universe?

According to Feynman, nothing directly measures energy. Energy is always calculated from other quantities. An indicator, such as the needle on a meter can multiply just as easily as an ancient slide rule, or a look-up table in a computer, or the multiplication table you've memorized in your head. Whenever you figure out how to "truly measure" power, be sure and call up your local university and tell the physics faculty what you've discovered. I'm

sure they'll all be very interested.

You really need to consider how ridiculous this statement is. Your
statement contradicts basic circuit theory and basic transmission line
theory.

What mechanism causes the cancellation? There is only one rearward steady
state wave flowing into the source. How can a cancellation occur with only
one wave? At any impedance junction energy is transmitted and reflected as
a function of the value of the reflection coefficient. 33.33 W of power
arrives at the source, 8.33 W is re-reflected. 25.0 W is "delivered" to the
source impedance. The total steady state power dissipation in the source
impedance is determined by the superposition of the forward and rearward
voltages in the source impedance. We're at a point where you are ignoring
simple circuit theory to convince yourself that you're correct.

What other rearward wave cancels the rearward voltage entering the source?

Steve

Gonna be a tough project. You would need a motorized crankup mast or
tower that would extend from 21 ft up to 167 ft. Then a selectable
tapped loading coil. Maybe relays could do the trick. The 21-167 ft
tower is going to be the fun part.
I won't even mention the needed good ground system... MK

> statement contradicts basic circuit theory and basic transmission line
> theory.

Nope it doesn't, Steve. Your RF diode contradicts basic transmission theory. You simply cannot have an impedance discontinuity that exists in one direction but not in the other direction. Either the impedance discontinuity exists in which case it causes re-reflections AND destructive interference or the impedance discontinuity doesn't exist in which case there aren't any re-reflections. You simply cannot have it both ways.

> What mechanism causes the cancellation?

Destructive interference.

> There is only one rearward steady state wave flowing into the source.

There is NO rearward steady state wave flowing "into" the source. Put your finger on the point "at" the source where the 8.33 watts of re-reflection occurs. That's the point where destructive interference occurs. You simply cannot have a point that causes 8.33 watts of re-flection only to have that point disappear at your whim when you don't like the results. That point is "at" the 150 ohm to 50 ohm transition point. It is not *in* the source impedance. In your drawing, it is *at* the '+' character just like it was in the earlier example. Reflection wave mechanics work even when there is no transmission line.

> How can a cancellation occur with only one wave?

There are two complimentary waves, Steve, just as there were in the earlier example. The 50/150 ohm discontinuity point cannot exist in only one direction. You say it exists long enough to cause 8.33 watts of re-reflection and then disappears. That is certainly a violation of the laws of physics. That impedance discontinuity point exists at

the '+' character in your drawing.

> At any impedance junction energy is transmitted and reflected as
> a function of the value of the reflection coefficient. 33.33 W of power
> arrives at the source, 8.33 W is re-reflected. 25.0 W is "delivered" to the
> source impedance.

No it isn't, Steve. The same point that causes the 8.33w to be re-flected
works in the other direction to cause a complementary 25 watt wave to
develop. IF THE REFLECTION COEFFICIENT IS 0.5, IT IS 0.5 IN BOTH DIRECTIONS!
Wherever it is that the generated forward wave sees the 50 ohm to 150 ohm
discontinuity is where the 25w of complementary wave originates. Your own
figures indicate that the 25 watts exist.

Please pay close attention: You add 75 watts to 8.33 watts to get the
forward power of 133.33 watts. The generator is outputting 100 watts.
Where is the 100 watts minus 75 watts? It's the very power we are
talking about that causes the destructive interference. Since you
allow energy to magically disappear and reappear somewhere else,
you cannot see the contradiction in your statements.

> The total steady state power dissipation in the source
> impedance is determined by the superposition of the forward and rearward
> voltages in the source impedance. We're at a point where you are ignoring
> simple circuit theory to convince yourself that you're correct.

It is not "in" the source impedance, Steve. It is "at" the source impedance.
A point "at" the source impedance is a 50 ohm to 150 ohm impedance discontinuity.
That impedance discontinuity is bi-directional. It CANNOT, as you say, act like
an impedance discontinuity in one direction and disappear in the other direction.
You have taken others to task for suggesting such a violation of circuit theory
and transmission line theory in the past. Please show us an example of a uni-
directional impedance discontinuity.

>dipole.
>
Here we disagree. For your statement about exactly equal currents in both legs of the dipole to be true, it requires that the whole system is symmetrical about its centerline - but it is not. One side of the dipole is connected to the center conductor, but the other side is connected to the shield. That is not symmetrical and can never be made so.

The practical test for symmetry is to stand a mirror up along the centerline of your drawing. Is the reflection in the mirror the same as what you see when you take the mirror away? No, it isn't.

To anticipate one possible reply (or something that might cross the minds of others reading this), it is not sufficient to say "make the coax thinner, and you can make the system near-enough symmetrical." That solution is unacceptable because our entire discussion hinges on that small but important difference between "near-enough" and "exactly".

So from my viewpoint, I'm continuing with

>Because of the requirement that the magnetic field due to the
>center-wire current and the magnetic field created by the return
>current on the *inside* surface must exactly cancel each other at the
>inner surface, the resulting conclusion is that *all* of the electron
>current from the left side must flow on the inner surface, and none of
>it flows on the outside surface, regardless of the impedance along the
>outside surface.
>
Half-agree. Re-quoting what you just said, but splitting it into two parts:

>Because of the requirement that the magnetic field due to the
>center-wire current and the magnetic field created by the return
>current on the *inside* surface must exactly cancel each other at the
>inner surface,

Fully agree, including the "exactly"... but not with the next part:

>the resulting conclusion is that *all* of the electron current from the
>left side must flow on the inner surface, and none of it flows on the
>outside surface,

To me, that implies something totally different.

My position starts from the requirement that the skin effect must happen at all surfaces that have an RF current flowing over them - regardless of the circuit configuration that makes those currents flow. This was proved by Davidson; I mailed Bill a photocopy of that result some years ago, and if anyone else is interested, a scanned copy of is still on my website at:
http://www.ifwtech.co.uk/g3sek/misc/skin.htm

Given the skin effect, the coax then behaves as three conductors: the two inside, very closely electromagnetically linked so that their currents are exactly equal and opposite; and the third one outside which is independent of the other two. The magnitude (and phase) of the outer-surface current will of course be determined by all the rest of the circuit conditions, but its existence as a separate current is undeniable.

Equally undeniable is Kirchhoff's law to account for all the electrons flowing at the junction between the three separate conductors: leg of dipole, inside of shield and outside of shield.

Recalling that the currents on the center conductor and the inside of the shield are always exactly equal, my own "resulting conclusion" is that the difference in currents between the two legs of the dipole (which must exist, due to the unavoidable asymmetry) will flow on the *outside* of the shield.

>regardless of the impedance along the outside surface.

The impedance along the outside surface of the coax certainly does affect the amount of current that flows. These things can happen because the outer surface of the coax has become part of the radiating system, so all analyses of the "antenna" must include that "third wire".

The transmitter is fully enclosed and floating in space, so that is a high-impedance point for outer-surface currents. If the coax is a half-wavelength long, there will be a high surface impedance at the feedpoint, so surface current s will be discouraged. If the coax is a physical quarter-wavelength long, that high impedance will invert to a low surface impedance at the feedpoint, so surface currents can flow more freely. The physical asymmetry at the feedpoint remains the same, but its electrical effect can be modified by changing the outer-surface

impedance at the feedpoint.

That is exactly what we do when we add a feedline choke. It increases the surface impedance at the feedpoint, and forces all currents in the system to readjust themselves to take account of this new condition. (The feedline choke also has effects inside the coax, but those do not change the effects on the outside.)

>This verifies the claim that all of the current on the outer surface is >due to electromagnetic induction,

Sorry, I think that is based on an incorrect assumption, and is oversimplified.

Whatever current there is on the outer surface, it must be consistent with *all* of the following:

* The requirement that RF currents will flow independently on independent surfaces (regardless of the circuit configuration that makes those currents flow)

* The exact equality of currents on the center conductor and the inside of the shield (equal and opposite, that is)

* Kirchhoff's law, applied at the end of the shield where three conductors join (all electron currents must be accounted for; none may leak away or be ignored)

* The physical asymmetry at the feedpoint, which means that the whole system is not symmetrical and the currents in the dipole legs are *not* exactly equal.

* The impedance presented to surface currents at the feedpoint (determined in this free-space example by the length of the feedline)

* However much electromagnetic induction is also taking place, in any respect.

It is impossible to identify any of these as either cause or effect - under the applicable laws of physics, they all must coexist.

What you can do is choose the order in which you apply things you do know, in order to deduce things you don't know.

There are many areas where this simple approach is incomplete - but incomplete is not the same as "wrong". I freely admit that my approach does not provide the deeper insights that Bill's approach does. Mine is strictly an engineer's approach, to tell me as much as I need to know in order to tackle the practical problems involving surface currents.

Ian, G3SEK wrote:
"---such meters (Bird wattmeters) have the peculiar property that the difference between the indicated forward and reverse powers is equal to the power delivered to the load, regardless of the actual load impedance."

Mission accomplished!

Ian also wrote:
"Any other so-called RF wattmeter that depends on sensing voltages and currents on the line is the same - it isn`t a true wattmeter because it doesn`t truly sense power."

That is not a disqualification. A speedometer measures neither distance nor time directly. It measures a proportional electric current. Same with a fuel gauge. It measures neither gallons nor litres.

Ian also wrote:
"The conversion from microamperes to indicated power takes place litterally on the scale of the meter---."

Same for MPH or 1/2-full. Accuracy is in the calibration.

Ian also wrote:
"That "power" calibration is only valid for a 50 ohm load [1].

The same is true in a sense for a speedometer. Change the wheel size and the speed indication is invalid. This is a matter of specification.compliance. The wattmeter impedance and the speedometer wheel size are specifications. If these change, recalibration is needed.

Ian also wrote:
"The sensor also contains a diode detector---."

R-F like a-c of any frequency neads to be rectified for display on a d-c instrument. Dynamometers have too much inductance to use at r-f and are insensitive.

Ian has in one short remarkable paragraph given a nice explanation of how the Bird wattmeter works. It includes how one direction is selected and the other is rejected, This is the key to how this instrument operates.

Ian also wrote:
"It generates two voltages one proportional to the RF voltage - one proportional to the RF current - which are added or subtracted. There is no multiplication of voltage and current, so there`s no power detection here..."

Wrong! My slide rule also adds and subtracts to multiply and divide, using scale lengths. The maker brags of accuracy assured by "engine divided" scales. It`s all a matter of callibration of scales.

Ian also wrote:
"The Bird wattmeter is very poor evidence for anybody`s argument because it does not truly measure watts."

Imperfect as the Bird is, it is the best instrument to indicate power commonly available to the amateur. Its operation indicating forward, reflected, difference power, and their locations, is more revealing than other commonly available instruments.

I beg to differ with Ian`s assessment of the Bird`s utility.

Best regards, Richard Harrison, KB5WZI

Bear in mind that the length of the antenna must
vary with each band -- therefore such a design is
not very practical. That's why we never hear of
a multiband 5/8 antenna.

Not at the source. There is no 50 ohm transmission line between the 50 ohm source impedance and the 150 ohm line in these simple examples. Impedance discontinuities are only relevant for the waves traveling INSIDE the 150 ohm transmission line. Simple circuit theory is used looking forward from the source into the transmission line.

> directional impedance discontinuity.
> --

Cecil, from the perspective of the source looking into the transmission line, there is no forward reflection coefficient. All the source "sees" is an impedance connected to it. The source does not distinguish between a fixed Zo load and a Zo transmission line. They look the same. There is no forward reflection coefficient looking from the source towards the transmission line. There is no reflection mechanism looking from the source into the transmission line. Reflections only occur for the forward wave arriving at the load and the rearward wave arriving at the source. In the initial state, the forward voltage delivered to the ZO impedance connected at the source is determined by simple voltage division between the source impedance and Zo. There is no reflection to create the wave cancellation you are claiming exists. If you can't get beyond this simple circuit understanding of what happens in the initial state then lets stop here.

Alternately, use your bi-directional impedance continuity at the source to describe the initial state voltage conditions in this example.

141.42 V --50 ohm Source Z---+ 150 ohm line ----+ 150 ohm load.

The 141.42 V source drives a forward voltage of 35.36 V across the 50 ohm source impedance and a forward voltage of 106.06 V into the 150 ohm line.

Nothing else happens in the forward direction. There are no reflections at the junction between the source impedance and the 150 ohm line (in the forward direction).

Hello Walt,
That is some of the very BEST Ham Radio news I have heard in a long time Walt. Thank you for posting it. It's going to bring many more people into the ranks. It also serves to establish at long last a "no-Morse code" license (I read about the "Morse appreciation" - test -) and should go a long ways to encouraging other countries to do the same. It is long overdue. I am also thrilled to see the new and correct nomenclature of "Hobby Radio" be used. Too many Hams make radio a religion and a life's philosophy. Especially hard-core CW advocates and many DX'ers. It is a "hobby" and the UK has it nailed 100% correctly.

Moreover your advice to ignore and purposely not make contacts with any of the new license holders once they get on the air is really silly. It makes you look like an asshole and an old curmudgeon fuck dick. I hope instead the new license holders ignore "YOU". They would be far better off to do so and thus never have to meet you or hear your prejudiced views on "Hobby Radio"

Have a nice day.....

> source into the transmission line.

I just realized what your basic mental blunder is, Steve. You start out analyzing the example using wave analysis. In the middle of the analysis, when it suits your ulterior motives, you switch to circuit analysis. You, of all people should know that is a no-no. Whatever analysis method is chosen to start with must be stuck with throughout the entire analysis. There are all sorts of examples where switching from wave analysis to circuit analysis in midstream will cause erroneous results just like the one you have encountered.

> Cecil, from the perspective of the source looking into the transmission
> line, there is no forward reflection coefficient.

That's because you switched from wave analysis to circuit analysis in midstream. That's a no-no, Steve. I'm surprised a PhD doesn't know that.

You must choose either wave analysis or circuit analysis to start with and stick with that decision throughout the entire analysis.

If you choose wave analysis, then there certainly exists a 50 ohm to 150 ohm impedance discontinuity seen by the source. It exists at the interface between the 50 ohm environment and the 150 ohm environment. Like I said before, wave analysis works just fine even when there is no transmission line present.

If you choose circuit analysis, there is no reflection coefficient, no reflected power, and no re-reflected power.

I can handle either analysis that you choose but I will not remain silent while you willy-milly switch from one type of analysis to another in

midstream for the purpose of obfuscating the results. You cannot set up
reflected power in one model and then in midstream, switch to another
model where reflected power is not allowed.

This is probably due to your plug-in to viewing the images expired.
The Patent Office posts their images in a format (TIFF it looks like)
that requires a commercial plug-in (or so one would think). The first
visit usually has my browser complaining of needing some add-on and
when I visit any particular site to satisfy that requirement, it is
painfully obvious that those to select from are all jockeying for
eventual cash outlay.

>elements.

This is consistent with the image I e-mailed you. And, of course,
wholly inconsistent with the discussion that precedes these postings.

>
>FIG. 2 shows a cross section of the support boom of a variable
>capacitance antenna detailing the structure of the variable capacitor
>portion and the remote tuning portion.
>

I did not bother to post you that cartoon straight out of Rube
Goldberg.

>FIG. 3 shows a rack and pinion movement for the remote tuning portion
>of a variable capacitance antenna.
>

The statement is enough, a drawing hardly counts for much in the
analysis of the antenna itself.

>FIG. 4 shows a variable capacitor portion for use with two elements.

The statement is enough, a drawing hardly counts for much in the
analysis of the antenna itself.

>Here , you talk of three dipole elements???? Multi elements????
>Can you see the contradiction between this antenna and what you are
>posting here as a description?

Well Mark, to be fair, Art has deliberately avoided its discussion for
the reasons he anticipated: it is much too elaborate compared to the
general idea.

>
>I about give up. Until I can get an EXACT picture of the antenna,
>there is no way I can make any kind of lucid comment on it.
and of course the remainder of your commentary reads like a descent
into hell.

Simply put, Art is not prepared to present anything except a vague
outline for a coupled antenna system. That has been played out long
ago.

I realize now what your perspective is on the initial state condition and the bi-directional reflection coefficient at the source. Unfortuantely, there are no "waves" in the source impedance. These examples involve simple voltage sources connected to a transmission line. They create voltage and current as a function of the effective load connected to them. The "waves" and your wave theory are only relevant in the transmission line. If you replaced the 150 ohm transmission line and 150 ohm load with a 150 resistor would you use wave theory to determine the voltage in the source impedance or circuit theory? I realize that your wave theory math would give the "correct" answer but it certainly does not represent what's physically happening.

I would suggest reading Johnson's text - Transmission Lines and Network. If you review chapter 4 you will see how the analysis is handled.

Take care Cecil, this discussion has digressed to a ridiculous level so I really will bow out.

That's why wattmeters have an associated Z0, usually 50 ohms. The addition
of signals proportional to voltage and current is only accurate from a
power standpoint if they have been calibrated to the proper Z0 environment.

Waves of zero length and same-cycle reflections work just fine with wave analysis, Steve. Your error is in adopting the wave model for half the example and then switching to the circuit model for the rest of the example. You simply cannot transfer reflected power from the wave model into the circuit model. Nice try though. I'm sure you managed to confuse a lot of folk who don't know that it is a violation of the rules to intermix models. But after violating the conservation of energy principle, what's one more violation, eh?

If you want to use the wave model, you must at least install an infinitesimally short piece of 50 ohm feedline between the source and the 150 ohm feedline. When you do that, the results are identical to the other example, just like I said from the beginning.

> I would suggest reading Johnson's text - Transmission Lines and Network. If
> you review chapter 4 you will see how the analysis is handled.

I read that book cover to cover in 1958. He does not go into the depth needed for this discussion. And I don't recall Johnson trying to intermix the wave model and circuit model. I have known that one cannot intermix models since the late 50's. When did you learn that? When did you forget that?

I would suggest that you get you a good book on the rules for modeling electronic circuits and transmission line.

This is an obviously true statement. It says "the
electron current that arrives at the shield
connection from the left side *MUST* be exactly
equal to the current that enters the right side
from the center lead". Since no electrons leave
the system, this has to be true, and symmetry has
nothing to do with it.

>> Because of the requirement that the magnetic field due to the
>> center-wire current and the magnetic field created by the return
>> current on the *inside* surface must exactly cancel each other at the
>> inner surface, the resulting conclusion is that *all* of the electron
>> current from the left side must flow on the inner surface, and none of
>> it flows on the outside surface, regardless of the impedance along the
>> outside surface.

This statement is a logical conclusion to the fact
that the mag fields cancel at the inner surface,
therefore the inner surface current *has* to be
identical to the center wire current. The outer
surface current does not contribute to the
cancellation at the inner surface.

Common mode currents, induced by electromagnetic
induction, are caused by asymmetry. The effect of
these currents is to modify the impedance of the
dipole(the outside surface becomes "like" a
parasitic element).

Hey! A better idea already! :-)

My only reason for mounting the remote tuner on the ground is that it will be a homebrew tuner, and the support will be mast, not tower. So I was hoping to keep it more accessible for tweaks and such.

It will be a homebrew tuner because I can't find any on the market that you can set the settings yourself. They only tune automatically, and only when transmitting. This will be for a pactor MBO where most of the time is spent scanning many freqs and bands, so I need to be able to "set up" the tuner without transmitting to it...

Other ideas are appreciated.

Well, you should read it again.

Page 19. "The sending end cannot know that the line is not infinite until the arrival of the first reflection from the receiving end; therefore, the line will initially look like an impedance Zo at the sending end. Using the voltage divider principle to calculate the initial sending voltage, we find

Eforward = Esource * Zo / (Zo + Zs)

[Cecil, this looks like circuit theory to me. I don't see where he uses a reflection coefficient here.]

A wave of voltage of this value travels to the receiving end, where it is reflected with the coefficient rhoR. The reflection travels back to the generator end, where it is reflected with the coefficient rhoS."

Page 98. "When the generator is first connected to the line, it sees an impedance equal to Zo until the arrival of the first reflection from the load. Therefore, for the first few moments the sending-end voltage [forward voltage] of the line will be Eg Zo / (Zo + Zg)." [Again, the circuit theory principle I use is not a problem].

The only place Johnson discusses reflection and re-reflection is WITHIN the transmission line. He never discusses your concept of wave reflection within the source and he frequently "mixes" circuit theory and wave theory within his examples and discussion of basic theory.

My analysis technique is consistent with every text on transmission line theory, so stop simply telling me that you're right and I'm wrong. Please site your reference where it is demonstrated that reflections exist within the source or generator (under these simple example conditions) as the source "forward" voltage first encounters the transmission line. Also site your reference that discusses the concept of rearward wave cancellation within the source (at the transmission line junction) to support your discussion.

Source record: 136958

I've been using the MFJ-1764 and MFJ-172 for a while and they've performed fine, but after a night of high winds, rain, lightning and thunder, I awoke to two bent antennas. The wind speed that night (August 2nd) was 21 mph with the highest gust being 42 mph. The 1764 was bent in half and the 1762's reflector was bent into an upside down V shape. I thought you might be interested in knowing how these antennas stood up in a moderate storm. If you go to http://www.wunderground.com/history/airport/KWRI/2002/8/2/DailyHistory.html, you will see the actual conditions that night in my area.

I was recently trying to decide which 2m/70cm yagi to buy and had narrowed it down to the MFJ-1768 or the Cushcraft A27010S. Because of my recent experience with these two MFJ antennas, I decided to give Cushcraft a try and have ordered their antenna.

I have for sale two Bilal Isotron antennas. Model 80 (80 meters) $70., and model 40 (40 & 30 meters) $60. Prefer pick up at Greenville, SC or add $8. each for shipping. Antennas have been assembled and used indoors only. Complete with original instruction manuals.

Johnson understood what he was doing and apparently you don't. There's nothing in wave analysis that prohibits a fixed impedance so he wasn't using circuit analysis at all.

> The only place Johnson discusses reflection and re-reflection is WITHIN the

He must have understood what he was doing. You obviously don't. I can't find my copy of Johnson at the moment so I don't have access to the book.

> My analysis technique is consistent with every text on transmission line

I'm right and you're wrong! :-) Please produce just one text on transmission line theory that says that 75 joules/sec plus 8.33 joules/sec equals 133.33 joules/sec. If you can produce that transmission line textbook, I will show you an author who is insane.

I think you missed the point with the transformer example. The voltages
on the two inputs don't add up to the voltage on the output if the
impedances are kept constant. To get Steve's results, the impedances
have to be changed. Changing the impedances is impossible inside a
transmission line. Therefore, Steve is missing some power. Did you
miss that point, Richard.

I'm glad you're delving deeper into this than ever before. I'm also
glad you admit that your method for getting

75w + 25w + 25w + 8.33w = 133.33w

is yours and yours alone. You just can't base your argument for that
25 watts reversing direction on conservation of energy. You should
call it CAM's destructive/constructive interference postulate until
you get a paper published.

> You guys remind me of the doctor when I say, "Doctor, it hurts when

Why do you think I'm backing off? Concepts such as wave components,
partial
reflection/transmission, and superposition are completely consistent

and compatible with conservation of energy. I'll continue to use these methods just like I did in computing all those component values in a previous post. I just disagree with your use of the conservation of energy principle to justify your speculation about that 25 watts reversing direction. As I said, the only thing that conservation of energy says about your problems is that all the power generated by the source is dissipated in the load. That's the only equation that conservation of energy needs to be balanced. The mechanism for how that power gets to the load is another source of disagreement.

> Take a look at the example I made up for Steve and tell us how the
> 25 watts of previously reflected power makes it to the load when

> in the forward wave. Can we at least agree that all the generated
> power that makes it to the load must have joined the forward
> power in the transmission line? How else can it make it from
> the source to the load?

I haven't looked at that problem, but we can agree that all the generated power that makes it to the load must have joined the forward power in the transmission line. We disagree on the mechanism for how it's done. I would bet that partial reflection/transmission with superposition of voltages/currents completely explains it. Call it "phantom waves" if you want. It works.

That is only true if you ignore the existence of the independent
outside-surface current, and/or ignore Kirchhoff's law.

>>> Because of the requirement that the magnetic field due to the
>>>center-wire current and the magnetic field created by the return
>>>current on the *inside* surface must exactly cancel each other at the
>>>inner surface,

The premise is good...

>>>the resulting conclusion is that *all* of the electron current from
>>>the left side must flow on the inner surface, and none of it flows
>>>on the outside surface, regardless of the impedance along the
>>>outside surface.

... but the conclusion is logically false. All that you are entitled to
conclude is that the currents on the center conductor and the *inside*
of the shield are equal and opposite. Nothing more.

The additional conclusion that "none of it flows on the outside surface" requires an additional assumption, namely your initial assumption that the currents on both legs of the dipole "*MUST* be exactly equal". Can you justify that, and also the statement that "symmetry has nothing to do with it"?

I'll agree, the MFJ antennas do not hold up well. Even my 5/8 wave 2 meter antennas suffered severe damage in a minor wind storm.... And they are far less cumbersome with regard to wind load. I can't recall now, the Model Number of the HF/6/2 meter MFJ. Strikes me that is one of those listed below. It was in good condition, having been given to me. I installed it. One storm later, it was trash. That was a few years ago. Our storms have gotten seemingly worse since then. So I can imagine what would happen today! I like some of MFJs stuff, but some leaves a lot to be desired.
The "antennas" - I would certainly not tackle again. Just my consumer opinion.

Richard Clark wrote:
"Indirect? How so?"

Richard Clark is the metrologist, not I, but I recall making the measurements. It requires measuring the temperature rise and the time that`s required in a particular volume of water. The heat added to the water is that dissipated by the electrical energy which produces it.

This involves reading the temperatures in and out of the water flowing through the device and timing the filling of a container of a particular volume. Then you compute. That`s a lot of beating around the bush. That`s not a direct indication such as noting the deflection of a spring, or reading the level of mercury in a manometer.

Best regards, Richard Harrison, KB5WZI

I don't know if it would be practical for you to build your own antenna, but I have just published a design for a trapless vertical that works on 20, 15 and 10 meters. The main vertical element is only 11 feet (3.3 meters) tall. If the radials slope downward (recommended but not required) you'll need a bit more height for the radials. I see no problem meeting the "15 ft. maximum height" requirement with this antenna, though. Performance on all three bands is roughly equivalent to a quarter wave ground plane.

"You cannot take two transmitters, each putting out 70.7 v at 1.414 a and sum the outputs to get 141.4 v out at 2.828 a. That`s getting 400 watts from two 100 watt transmitters."

Cecil is right, of course, because the transmitters are incapable of more than 100 watts each.

There are audio chips that are capable of more output than they produce into a specified 8-ohm load with a 16-volt collector supply. Such chips may supply 1/2 amp or 2 watts into 8 ohms. With the equivalent of a series connection, two of these chips can double the voltage across the load and this doubles the current too. This produces 8 watts in the 8-ohm load. But, this is only because the chip was capable of twice the current output, a full amp.

With power limited r-f transmitters the story is different. Take it from me. I`ve paralleled two 50 KW transmitters and the most I could reasonably get out was 100 KW.

Best regards, Richard Harrison, KB5WZI

After occasionally tuning across the CB frequencies in an attempt to see what people are so steadfastly defending, I have routinely heard very little verbal exchange of ideas. Primarily I see radios being used as a sort of cathartic tool of cowards for whipping on other anonymous radio signals without fear of a knuckle sandwich, or even worse, a tool for broadcasting deranged and psychotic outbursts and incomprehensible word salads, gibberish and other exhibitions of lunacy.

Perhaps this is a local problem, in which case I apologize to those who may have been driven off for meaningful exercise of the 1st Amendment here, or in other areas those who have truly been able to.

Otherwise what's to "talk" to?

: Hello Walt,
: That is some of the very BEST Ham Radio news I have heard in a long
: time Walt. Thank you for posting it. It's going to bring many more
: people into the ranks. It also serves to establish at long last a
: "no-Morse code" license (I read about the "Morse appreciation" - test -)
: and should go a long ways to encouraging other countries to do the same.
: It is long overdue. I am also thrilled to see the new and correct
: nomenclature of "Hobby Radio" be used. Too many Hams make radio a
: religion and a life's philosophy. Especially hard-core CW advocates and
: many DX'ers. It is a "hobby" and the UK has it nailed 100% correctly.
:
: Moreover your advice to ignore and purposely not make contacts with
: any of the new license holders once they get on the air is really silly.
: It makes you look like an asshole and an old curmudgeon fuck dick. I
: hope instead the new license holders ignore "YOU". They would be far
: better off to do so and thus never have to meet you or hear your
: prejudiced views on "Hobby Radio"
:
: Have a nice day.....

Message-ID: <3D599AF7.9050003@eznec.com>
Source record: 136876

We've had this discussion on this newsgroup before a number of times. If anyone is interested, I posted the results of some experiments which clearly show current on both the inside and outside of a coax cable in the absence of mutual coupling to any antenna. All currents are fully explained by simple circuit theory with the principles being described by Ian.

You should be able to find the postings with a Google search. The topic was "What's the difference.....", and the first results were posted on May 1, 2001. A correction and further discussion took place on several following days.

Hi Richard,

That is hardly indirect, but I can understand your logic (must be my weather-man background ;-)

The Hewlett Packard model Calorimeter was the most accurate Wattmeter available up to 1 GHz compared with most (read ALL) "indirect" meters of the 1950's-1960's.

Hi David--

Nice work, but not unique. As I recall, Dr. Tom of Force 12 used interleaved spiral end-loading for a multiband verical several years ago (the Z3??), and so have others. I presently have a 12-foot self-supported OCFD design on the roof covering 7 bands (20-2 meters) that's 12-feet high. Welcome to the neighborhood.

VE9SRB wrote:
> Its been fun. Take care Cecil.

All you have to do to convince me that you are arguing in good
faith is to present a reference that agrees with your power equation:

75w + 8.33w = 133.33w

You have taken Walter Maxwell to task many times for his "virtual short"
which seems to operate as some sort of RF diode. I don't agree with
Walt's "virtual short" but your impedance transition that presents
a 150/50 ohm transition to reflected waves but doesn't present a
50/150 ohm impedance transition to forward waves is exactly the
same concept as Walt's "virtual short". So, Steve, you wind up defending
yourself with the the same argument that you chastised Walt for
using. The readers are left to draw their own conclusion.

Hi Richard,

Right as rain, both in the practical failure and the practical
application of stretching a Watt. It also illustrates the driving
mechanism of Cecil's (unstated, but certainly counted on condition of
limited sources) that has collapsed at other stages like the failure
of the Transformer metaphor to sustain only ONE outcome. Such myopic
constraints lead to t'aint so-t'is so types of argument being
whipsawed by these simple errors.

Hey, guys, I appreciate your good intentions. However, only three out of a dozen or more responses were what I asked for in the message below. The majority of others were telling me why this won't do any good or to contact Hy-Gain, etc. We've already tried Hy-Gain and MFJ.

Our P&Z is in a small mountain village, not a big, sophisticated city. We have already had the "what's relevant?" conversation with the planning director and the village attorney. TESTAMONIALS ABOUT HY-TOWERS THAT HAVE SURVIVED STRONG WINDS IS QUITE ADEQUATE FOR THEM AND WILL CARRY A LOT OF WEIGHT.

So, with all due respect... please save your opinions as to why this information is useless.

Thanks... Ed, W5EJ

Bill, my knowledge is so old I don't even remember when I learned it. Doesn't 75 joules + 25 joules + 25 joules + 8.33 joules = 133.33 joules??? Isn't an equation like that what it takes to satisfy the conservation of energy principle? You, yourself, broke the component waves down into voltages, currents, and powers. Your results agree exactly with mine. I am amazed that you didn't take the next small step in logic. Someone has to think original thoughts for the first time. Why not join me in thinking the unthinkable?

Bill, you came up with those above power components. I left them out of my posting and you independently came up with them. To refresh your memory:

75w the part of the 100w of source power that is not reflected from the 50/150 ohm transition point, i.e. the part that passes through the 50/150 ohm junction and is not reflected. This is the 75w in Steve's energy equation.

25w the part of the 100w of source power that is reflected from the 50/150 ohm transition point. This is left out of Steve's energy equation.

8.33w the part of the 33.33w of reflected power on the 150 ohm T-line that is re-reflected from the 150/50 transition point. This is the 8.33 watts in Steve's energy equation.

25w the part of the 33.33w of reflected power on the 150 ohm T-line that is not re-reflected from the 150/50 transition point, i.e. the part that passes through the 150/50 junction and is not re-reflected. This is left out of Steve's energy equation.

The above four components are all the power that can contribute to the forward wave which we know is 133.33 watts. Don't you think it odd that 75w + 25w + 8.33w + 25w adds up to exactly 133.33 watts, the exact amount of energy in the forward wave on the 150 ohm line? Don't you think it odd that 75w + 8.33w doesn't add up to the amount of energy in the forward wave????

> Why do you think I'm backing off? Concepts such as wave components,
> partial reflection/transmission, and superposition are completely consistent
> and compatible with conservation of energy.

75 joules/sec + 8.33 joules/sec = 133.33 joules/sec is consistent with
the conservation of energy principle?????? Shirley, you jest. There is
not enough energy in just those two waves to support the 133.33 joules/sec
forward wave. Can you furnish a reference that says that 75 joules/sec
plus 8.33 joules/sec equals 133.33 joules/sec?

> As I said, the only thing that conservation of
> energy says about your problems is that all the power generated by the
> source is dissipated in the load.

Sorry Bill, that's not the only thing it says. Indirectly, it says that
energy cannot make it from the source to the antenna without traveling
through the transmission line. That should be intuitively obvious to
the most casual observer but Steve left it out of his energy equation.

> I haven't looked at that problem, but we can agree that all the
> generated power that makes it to the load must have joined the forward
> power in the transmission line.

Then how can you support the equation that 75w + 8.33w = 133.3w???
If there are only 83.33 joules/sec available how in the world do we
wind up with a total of 133.33 joules/sec????? Where did the extra
50 joules/sec come from?
--

Well, you obviously haven't been paying attention to what Steve has been
saying. He can take two signals of 1581v at 31.6a and "add" them to get 3162v
at 63.2a. Your two 50 KW transmitters wind up outputting 200 KW. That's how
he gets 133.33 watts out of adding 75 watt and 8.33 watt signals.

Source record: 136887

I haven't been following this thread carefully, but glance at it once in a while. I'm bemused by the casual way powers are added like they're D.C. Steady state powers aren't D.C., but vary with time.

Furthermore, consider two superimposed waves, one with V1, I1 and the other V2, I2 (all sinusoidal functions of time). The powers in the waves are P1 = V1 * I1, P2 = V2 * I2, where P1 and P2 are functions of time. The total power at the point of superimposition = Pt = (V1 + V2) * (I1 + I2) = V1 * I1 + V2 * I2 + V1 * I2 + V2 * I1. This is clearly not the sum of P1 and P2 except in some very special cases.

I find transmission line analysis to be pretty simple. But then, I avoid creating traveling power waves, then adding them up like D.C. Once you begin doing that, you can reach about any conclusion you'd like, and will only be right if you're really lucky. It's a lot more direct and productive to add forward and reverse V and I waves, since it's really the fields that are propagating. If you want to know the power at any point, simply multiply the superimposed waves at that point. That's the way I do it, anyway, and have never had any problem understanding the results.

Cecil, this is an aside and not a question related specifically to our examples. You like to discuss energy based a delivered transmitter power. If a 100 W transmitter delivers 100 W of power to a transmission line system in the steady state, how much total energy is in the transmission line system?

Steve VE9SRB

Apple's Quicktime will do it.
Innomage's InterneTiffX (v. 3.0?) is another good option.

Both are free in their basic versions (all you need).

Apparently the TIFF format is a treaty issue.

Which is exactly why it is impossible, Roy, given two and only two waves.
Take the following simple example based on a transformer.

Primary #1, 100 volts at 2 amps
Primary #2, 100 volts at 2 amps
Secondary 200 volts at 4 amps into 50 ohms

Is this possible? If not, why is it possible in a transmission line?
Clearly, in the above example there is not enough energy being supplied
to the transformer primaries to obtain 800 watts output. What is the
best we can do driving 50 ohms with the secondary? Hint: It's not 200
volts at 4 amps.

Where is the extra energy coming from that allows a transmission line
to react different from the transformer? Steve would have us believe
there is no extra energy. If no extra energy is needed, why can't we
obtain the above output from the transformer? If extra energy is needed
in the transmission line, where does it come from?

Build a properly decoupled J-pole or ground plane, up high and in the
clear. The gain differences between 1/4 wave, 1/2 wave, 5/8 wave, etc.
aren't as important as keeping teh antenna above and far away from
anything that could block the transmitted signal or interfere with
reception. For best results keep away from computers, televisions,
other electronic noise-makers, or any wire attached to one.

The validity, let alone necessity, of using transformers to explain transmission line phenomena escapes me, unless some weight is being put on the fact that both start with the same five letters. But I find transmission line phenomena easy to understand without the analogies, and I don't have time for this silliness. So I'll return you to your regularly scheduled programming. Have fun.

2856. Help with 20 meter 1/2 wave Vert

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-14 02:31:00 UTC
From: WD4LVO <wd4lvo@bellsouth.net>
Message-ID: <09r69.20685$g47.1136925@e3500-atl1.usenetserver.com>
Source record: 136820

I have some sections of a vertical antenna that I was hoping I can make a 14.000 - 14.060 MHz 1/2 wave antenna out of. The pieces I have are as follows:

1 section is a 1inch dia 6ft long
2nd section is a 3/4 dia 6ft long
3rd section is a 13inch piece of 1/2 pvc pipe that I could wind a loading coil on
4th section is a 9ft long whip

I have randomly tried to wind some wire on the short 13inch piece after the first two sections that are 12ft high and have not been able to match around 14 mhz. I might have to make the loading coil longer?
I only plan to deploy the antenna at
the destination, more like a field station ant so lenght is not a problem. I have a 1/4 wave now and
was looking to make a 1/2 if possible out of the pieces. I only need it to cover the cw portion of 20 meters. I was wondering if it was possible to make one out of my existing pieces, need some dimensions and loading coil windings.
Need some help in figuring the number of turns for the loading coil and gauge of
wire. I have the whole thing mounted ontop of a pickup truck. removable of course, I would like to achieve at least a 1/2 wave with this setup or 5/8 wave.
I don't know if it will help over a quarter wave when all will be using is a QRP rig.

Thanks Ozzy -WD4LVO.

Well, its cable TV and I am seeing big RF off the cable sheathing
itself, as I am seeing from all grounded conductors in the part of the
house near the dipole. I have yet to test whether it affects a TV
playing a videotape. My plan is to put ferrite toroid chokes where I
must.

Tom, KA6RUH wrote:
"How did you isolate thetransmitters so that they didn`t load one another--?"

I drove both transmitters from the same oscillator and combined their outputs through a hybrid ring. It worked well. May have been more than was needed.

Aren't you even curious as to why you can send two identical waves
into a transmission line and double the voltages while doubling the
currents and you cannot do that with a transformer? Shouldn't we
replace all the transformers with transmission lines since we can
get more voltage and more current out of the transmission lines than
we can get out of transformers?

Some readers are more familiar with transformers than transmission lines. Few are more familiar with transmission lines. Ideally both are lossless, and you get no more energy out than you put in for either device as both are passive. That is, neither has an inherent energy source beyond its external excitation. Further similarities are that both can transition from balanced to unbalanced and both can change impedances.

Transformers are accepted without argument (maybe everywhere but here) as having a real voltage and current product which is the same on the output as on the input. This is true of transmission lines too. I guess that Cecil`s point is that there is no inherent energy source in the transmission line to boost real power. So, any real product of voltage and current which exceeds the power input is a mistake.

Good advice. I have been doing it exactly that
way for years. It's not easy. You have
to be careful. You may be right about the
polarization. That would explain the random
favoring of one antenna.

Cecil, while you are at the library, get their copy of Reflections II and read through Chapters 17, 23 and 24. Won't take long . . .

Walt is saying the same thing that you are about how the rearward-traveling reflected wave is re-reflected back to the load, courtesy of a properly adjusted transmatch, stub or reflection generator of your choice. He discusses several varieties.

Also, find a copy of the January 1995 issue of CQ and see Warren Bruene's article on pages 13-17 entitled "Reflected Power Stays in the Coax" in which he explains why reflected power does not make it past the tuner input where it is re-reflected by merging at that plane with the incoming forward wave of the delivered power from the transmitter.

Steve has in past discussions with Walt Maxwell pooh-poohed the concept of a virtual short or open as a reflection generator. While Walt's terminology might not be realistic or appealing to some, his analysis of the currents and voltages associated with the incoming forward wave and the reflected wave that has passed through the tuner, or stub or whatever, does indeed confirm that "something" takes place at the tuner input plane when the two wave fronts meet. And that "something" is the mechanism for re-reflecting the original reflected wave from the load. He demonstrates that the currents and voltages have the proper phases to combine constructively with the incoming forward wave such that the energy in the reflected wave is not redirected back through the tuner as a component of the total forward power.

The final exam for re-reflected power is simply that the coax between the tuner and transmitter shows no reflected power traveling from the tuner to the transmitter, hence the reflected wave must have been re-directed in the tuner back to the load. The second part of the exam is to observe that after steady-state conditions are achieved, the forward power in the feedline to the antenna exactly equals the delivered power plus the re-reflected power - all assuming, of course, lossless lines and components. Walt takes loss into account, so it is not all a fairy tale.

>more than 100 watts each.

Sure you can - it's a classic two-tone test setup. With equal RF levels at say 1kHz apart, you get a composite waveform that shows the beat between the two carriers. The apparent 1kHz modulation comes from strictly linear addition of two sine-waves (which you can easily prove if you look at the waveform in detail, or with a spectrum analyser).

Vector addition gives 400W peak envelope power - defined as the power in the largest complete RF cycle, in this case at the peak of the 1kHz waveform - and tending towards zero in the smallest RF cycle at the trough.

Looked at in the frequency domain, you still have two independent 100W carriers, so certainly you get 200W average. But in order to get the correct average from the time-domain waveform, you have to average over the whole period of the composite waveform (in this example, 1 millisecond).

It is true, but misleading. The current can arrive at the shield
connection via two paths - the leg of the dipole and the shield.

You can show this by removing the dipole leg. The outside of the
shield then functions (as well as possible) as the second leg of
the dipole. The two currents inside the coax must still be equal.

> out of his energy equation.

Ignoring impedance matching problems, try looking at it by using batteries instead of transmitters. If you connect the batteries in parallel, you have twice the current at the original voltage. If you connect the batteries in series, you have twice the voltage at the original current.

In both cases, you get double the power available than what is available with one battery.

Shouldn't the same analysis be valid for RF transmitters?

Hi,

Try one of the MAR-n MMIC's from Mini Circuits. They
come with a variety of frequency spreads, gains and IP3
figures. If you can get the input circuit right, they are
easy to use and freely available. A search using
'amplifier' and 'mar-6' should bring up a PDF data sheet.

Cheers - Joe

Hi,

OOPS! - I should have said that the noise figures are
not that hot at about 5dB but generally at HF that is not a
limiting factor.

Cheers - Joe

Tony,
I don't think I'd go there! Using a mobile home
for the counterpoise isn't just asking for RFI problems,
it's begging for them. Not just for your self, but for
all your neighbors who also live in mobile homes close
to you. The 'shell' of a mobile home is rarely grounded.
'Doc

Steve is right about one thing. The reflected power is technically not 100%
re-reflected. The reflected power is 100% *re-directed* through two processes.
The first process is normal re-reflection at a physical impedance discontinuity.
The second process is wave cancellation (destructive interference) of two
out-of-phase waves through the process of superposition. Walt lumped
those two phenomena into the same bag, called it "100% re-reflection", and
wrote "virtual short" on the bag. Obsessing on the difference between
"re-reflected" and "re-directed" may seem like picking a nit. But on the
single point that reflected power is, technically speaking, not 100% re-
reflected, I would have to side with Steve. Surprise! That doesn't mean
that I will ever accept Steve's equation: 75w + 8.33w = 133.33w

I didn't simply say you can get more voltage out of a transmission line,
Roy. I said you cannot double the voltage in a transformer WHILE
AT THE SAME TIME doubling the current without supplying more power
to the inputs. Steve can double the voltage in a transmission line
WHILE AT THE SAME TIME doubling the current without supplying more
power to the line. That makes a transmission line extremely superior
to a transformer and means that, for the sake of efficiency, all
transformers should immediately be replaced with transmission lines.
Doing so would solve all our energy problems with energy to spare.

Source record: 136824

Lithium grease isn't good for this application.
The following is a list of paste and grease-like products for the prevention
of oxidation of aluminum in electrical connections and antenna
installations: (Prices could be out of date)

Manufacturer:
Butternut Electronics Company
831 North Central Avenue
Wood Dale, IL 60191
Tel: (708) 238-1854
Fax: (708) 238-1186
Product Name: Butter-It's-Not
Source: Direct if not stocked by local authorized dealer.
Price: $3.50/ Envelope
NOTES: Contains copper dust in a molybdemum suspension.
LOCAL NOTE: This one gets really good press from those who have used it.

Manufacturer:
GB Electrical
6101 N. Baker Road
Milwaukee, WI 53209
Tel: 1-800-558-4311
Product Name: OX-GARD
Source: Available from many electrical supply houses and retail
outlets such as Sears, Home Depot, Ace and True Value
Hardware stores. No Factory direct sales.
GB catalog number OX-100B.
Price: Approximately 3.00/ 1-oz tube

Manufacturer:
Ideal Industries, Inc.
Becker Place
Sycamore, IL 60178
Tel: 1-800-435-0705
and: 1-815-895-5181
Fax: 1-800-533-4483
Product Name: NOALOX
Source: Distributors (Call 800 number for nearest one)
Price: Ideal list price $2.58/ half oz tube (#30-024) and
$8.64/8oz bottle (#30-030).
NOTES: Also available from many electrical wholesale supply houses.
No factory direct sales. Contains zinc particles suspended
in a carrier.

Manufacturer:
KLM Antennas Inc.
PO Box 694
Monroe, WA 98272
Tel: 1-360-794-2923
Fax: 1-360-794-0294
Product Name: Conductive Paste
Source: Factory direct and larger dealers.
Price: $3.50 plus shipping & handling/ 1 ounce containers
NOTES: Anti-seize thread compound Hi-Temperature MIL-A-907E.
Contains copper and graphite flakes suspended in a petroleum
base. Manufactured for Mirage/KLM by Chemical Commodities
Agency, Inc. of Highland, CA per MIL-A-907E.

Manufacturer:
Sanchem, Inc.
1600 S. Canal Street
Chicago, IL 60616
Tel: 1-800-621-1603
Out of State: 1-312-733-6111
Fax: 1-312-733-7432
Product Name: NO-OX-ID
Source: Direct from Manufacturer
Price: $11/16oz can or $8.80/8oz tube (plus shipping)
Minimum order - $35
NOTES: NO-OX-ID comes in several consistencies. NO-OX-ID "A" and
NO-OX-ID "A-Special" are suitable for most antenna installations.
NO-OX-ID "A-Special" is similar to NO-OX-ID "A" but has a small
amount of solvent added for ease of application.

Manufacturer:
Thomas & Betts Company
1555 Lynnfield Road
Memphis, TN 38119
Tel: 1-800-888-0211
Fax: 1-800-888-0790
Product Name: Aluma-Shield
Source: No direct factory sales. Available from many electrical
supply distributors.
Price: Approximately $11.44/ 8oz can.
NOTES: Customer may call 800 number for location of nearest distributor.
Contains zinc particles suspended in a petroleum base.

Manufacturer:
Burndy Electrical
101 E. Industrial Park Dr.
Manchester, NH, 03108
Tel: 1-800-346-4175
Fax: 1-800-346-9826
Product Name: Penetrox (PEN-A)
Source: Electrical wholesalers
Price: Approx. $6/ 3oz tube

NOTES: Zinc particles suspended in a natural based compound.
LOCAL NOTE: Loaded with metal, needs a lot of stirring before use with a stick etc., seems to work well on sliding, telescoping aluminum elements.

Manufacturer:
Ilsco Corporation
4730 Madison Road
Cincinnati, Ohio 45227
Tel: 1-513-533-6200
Fax: 1-513-533-6274
Product Name: DE-OX
Source: No factory direct sales. Available from electrical supply wholesalers and distributors. Customer may call for nearest distributor.
Price: Approximately $2.90/ 1oz, $4.90/ 4oz and $7.30/ 8oz squeeze bottle.
NOTES: Used in the electrical trade for Al/Cu and Al/Al connections. Green colored grease with no noticeable particles in suspension.

Manufacturer:
Antennas West
PO Box 50062
Provo, Utah 84605
Tel: 1-801-373-8425
Fax: 1-801-373-8426
Product Name: Goose Grease
Source: Factory direct sales only.
Price: $1.00/ 1oz + and $1.00 p&h.
NOTES: Transparent silicone grease. Antennas West also recommends this product for ground rod clamp connections.

Manufacturer:
Mosley Electronics, Inc.
10812 Ambassador Blvd.
St. Louis, MO 63132
Tel: 1-800-966-7539
and: 1-800-325-4016
and: 1-314-994-7872
Fax: 1-314-994-7873
Product Name: 1) Mosley Penatrox (Conductive Grease)
2) Weather Guard (Clear spray coating)
Source: Factory direct sales only.
Price: Mosley Penatrox- $4.45 / packet + postage.
Weather Guard- $12.75/ 8oz spray can + shipping
NOTES: Mosley Penatrox is a grease-like product. Weather Guard is a clear spray especially recommended for marine and coastal environments. Weather Guard cannot be shipped via the post office; UPS required.

Manufacturer:
Loctite Corporation
1001 Troutbrook Crossing
Rocky Hill, CT 06067-3910
Tele: 800-842-0041
Product Name: Permatex ANTI-SEIZE LUBRICANT
Source: Many Automotive Supply Distributors
Price: N/A
NOTES: Comes in 1 oz squeeze tube, 8 fluid oz brush top container,
and a 12 oz aerosol can. Can be used on the threads of
U-bolts to prevent "seizing, galling, and corrosion."
It aids in the disassembly of the the antenna's hardware.
Not for use on electrical connections. The part no. on
a 1 oz tube is 133A.

ICE of Indianapolis also makes conductive paste for this application.

Yes, but I was using average power in my statement. You don`t have to
modulate to make a peak power observation. In a single sinewave the peak
power is exactly 2x the average because 1.414 times the volts multiplied
by 1.414 tines the volts produce twice the average power as a peak
power. It`s already there if you would like to make a peak power
observation.
Average power is half the peak power, as everyone should already know..

Nope, it's a short (assuming perfect components) but it's not virtual.
A virtual impedance is when you look into a 1/2WL piece of 50 ohm
line and detect the conditions existing at the load, 1/2WL away.

I do believe you have misunderstood what I said.

In the transmission line, Steve adds 106.066v at 0.707a (75w) to
35.355v at 0.236a (8.33w) and obtains 141.4v at 0.943a (133.33w)
without any additional energy.

It is impossible to do that with a transformer. That's makes the
transmission line much, much more efficient than a transformer.
The efficiency of a perfect transformer is only 100%. The efficiency
of Steve's transmission line is 160%. We need to convert all of
our transformers over to transmission lines as soon as possible.
That would be much more effective than solar power or wind power.

2891. Ladder-line Orientation?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-14 16:18:23 UTC
From: wa2si@arrl.net
Message-ID: <b7d1465c.0208140818.4532f9a0@posting.google.com>
Source record: 136832

I have a 40-meter doublet fed with approx. 40 ft. of 600 Ohm ladder-line. The antenna crosses my roof and the ladder line slopes down to the edge, where it then drops down to a 4:1 balun suspended just outside my shack window. I'd like to raise the balun up approx. 7 or so ft. so the ladder-line no longer rests on the roof's edge. This would cause the ladder-line to kinda run horizontal over to the side of the house and only require approx. 30 ft. to reach the balun. My question is whether or not the horizontal vs. vertical orientation of the ladder-line adversely affects the antenna system's performance in any way? To be honest, the ladder-line from the antenna to the roof's edge is at a pretty shallow angle as it stands now. I thought I'd ask anyway. Thanks in advance.

2894. Email to Doug Smith, kf6dx, QEX Editor

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-14 16:38:05 UTC
From: CAM <w5dxp@hotmail.com>
Message-ID: <3D5A876D.B9100406@hotmail.com>
Source record: 136835

Here's an email that I just sent to Doug Smith.

Attn: Doug Smith

Hi Doug, I'm Cecil Moore, W5DXP, ex-W6RCA. It seems that the reflected power debate has gone to unnecessary lengths in time and verbiage. Both sides of the two arguments being presented are flawed. My ideas are somewhere in between and are perfectly consistent with transmission line theory and the conservation of energy principle.

Here's the example that we have been using:

100w XMTR---50 ohm feedline---+---1/2WL of 150 ohm feedline---50 ohm load

The reflection coefficient at the 50/150 ohm junction is 0.5.

Attached is a phasor diagram of what happens at the match point. That same phasor diagram can be viewed on the web at:

http://www.qsl.net/w5dxp/Z0MATCH.GIF

The components on the phasor diagram are as follows:

1. (100 watts) forward power on the 50 ohm line coming from the generator. These two voltage and current phasors are drawn at 90 degrees because it is easy to draw. Thus that 90 degrees becomes our reference for all the other voltage and current phasors.

2. In accordance with accepted wave reflection mechanics, (25 watts) of the source 100 watts is reflected back toward the source at the match point.

3. In accordance with accepted wave reflection mechanics, (75 watts) of the source 100 watts flows through the match point and joins the forward wave, in phase, on the 150 ohm line.

4. The steady-state power reflected from the load is (33.33 watts).

5. (8.33 watts) of that 33.33 watts is re-reflected at the match point in accordance with accepted wave reflection physics.

6. (25 watts) of that 33.33 watts flows through the 150/50 junction in accordance with accepted wave reflection mechanics.

Component number 2 and component number 6 are out of phase. Their voltages are 180 degrees out of phase and their currents are 180 degrees out of phase (see phasor diagram). When these two waves encounter each other, they cancel, or more correctly they engage in destructive interference.

According to the principle of the conservation of energy, when there is a destructive interference pattern established, there must also be a constructive interference pattern established somewhere else. Since the destructive interference is completely confined to a piece of coax, the constructive interference must be established at essentially the same point as the destructive interference.

The destructive interference pattern involving the two 25 watt waves cancels any energy flowing back toward the source. We can verify this with a wattmeter. The 50 joules/sec (watts) involved in the destructive interference pattern MUST appear somewhere as it cannot disappear from the universe. It is not traveling back toward the source. That leaves only one direction that it can take. The 50 joules/sec involved in the destructive interference changes direction and heads back toward the load (it has no other choice). It thus becomes constructive interference and joins the forward wave on the 150 ohm line.

The appropriate voltage equation is:

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

The last two terms in the sum are the voltages involved in the destructive interference.

The appropriate current equation is:

0.707a + 0.236a + 0.707a - 0.707a = 0.943a

The last two terms in the sum are the currents involved in the destructive interference.

Multiplying voltages by currents yields the power equation:

75w + 8.33w + 25w + 25w = 133.33w

And there you have it. Everything is perfectly consistent with transmission line theory and the conservation of energy principle.

At the match point, all the reflected power is re-directed back toward the load through two processes, one of re-reflection and the other of cancellation (destructive/constructive interference).

Hi Cecil,

How do you know the correct current equation isn't:
0.707a + 0.236a + 0.707a - 0.707a + 0.707a - 0.707a + 0.707a -
...
0.707a + 0.707a - 0.707a + 0.707a - 0.707a + 0.707a - 0.707a +
0.707a - 0.707a + 0.707a - 0.707a + 0.707a - 0.707a = 0.943a

Both sides of the equation balance and make as much sense as yours.
Can you prove otherwise? I didn't think so.

Because there are no component waves to support all those currents.
I have only shown the currents of the actual component waves that
exist in reality. The forward energy wave on the 150 ohm line is
the combination of four and only four wave components.

> Both sides of the equation balance and make as much sense as yours.
> Can you prove otherwise? I didn't think so.

You know one cannot prove a negative, Richard. I have made assertions.
If you choose, it is up to you to disprove my assertions. Your above
diversion doesn't disprove anything. It just means you have fantasized
a bunch of currents into existence in your mind that don't exist in
reality. I have not done that.

One rule you need to adopt for yourself is don't add in more currents
than exist in reality.

Each EM wave component in a transmission line has an associated voltage,
current, characteristic impedance, and energy (power). These wave components
can be identified separately. Don't make up currents for non-existent wave
components and you will keep yourself out of trouble.

Message-ID: <3D5A97D5.569F7582@hotmail.com>
Source record: 136843

Here's a quiz for all you superposition gurus. The Superposition Theorem states that energy waves can be superposed at one end and de-superposed (decomposed) at the other end of, for instance, a transmission line.

Steve superposes (106.066v at 0.707a) and (35.355v at 0.236a) to obtain a superposed wave of (141.4v at 0.943a).

The superposition theorem says these same components can be de-superposed (decomposed) back into the original components. So we should be able to obtain (106.066v at 0.707a) and (35.355v at 0.236a) at the output end of the circuit.

Can anyone show me how to decompose (141.4v at 0.943a) into the original two (and only two) signals?

From the IEEE Dictionary: "superposition theorem - States that the current that flows in a linear network distributed in any manner whatsoever throughout the network is the sum of the component currents at the first point." The same holds true for voltages.

We all agree on the voltage and current components. We need to move beyond that point. The disagreements arise from our interpretation of how forward voltages and currents combine and how the resulting forward power is determined from that combining.

Independent of *any* specific example conditions, two forward voltages of 106.06 V and 35.34 V in a transmission line, added in phase, will always result in a total voltage of 141.1 V and the total forward power in a 150 ohm line will always be 133.3 W. Nothing will ever change that, regardless of how the example is set up.

2908. Re: Superposition quiz

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-14 18:30:32 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D5AA1C8.20202@eznec.com>
Source record: 136849

What textbooks are you reading?

In _Network Analysis_, Van Valkenburg says that:

". . .we observe that we may consider each of the transform sources [in a network] one at a time and then add the partial responses to get I2(s) [the total transform current]. This is, in essense, the superposition principle. . . A given response in a network resulting from a number of independent sources (including initial-condition sources) may be computed by summing the response to each individual source with all other sources made inoperative (reduced to zero voltage or zero current). This statement describes the additivity property of linear networks."

A more succinct definition can be found in _Introductory Circuit Analysis_, where Pearson & Maler write:

"Superposition applies to these [driving function/response] equations. This means that if x1 is the response to f1(t) and x2 is the response to f2(t) then (x1 + x2) is the response to f1(t) + f2(t)."

Specifically speaking of the superposition of fields, Kraus writes in _Electromagnetics_:

"The Electric Field of Several Point Charges and the Principle of Superposition of Fields. Since the electric field of a point charge is a linear function of the value of the charge, it follows that the fields of more than one point charge are linearly superposable by vector addition. As a generalization, this fact may be stated as the principle of superposition applied to electric fields as follows: The total or resultant field at a point is the vector sum of the individual component fields at the point."

No mention is made in any of these texts of a requirement or method to "de-superpose" voltages, currents, responses, waves, or fields.

2909. Supergain of monopole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-14 18:57:48 UTC
From: fractenna@aol.com
Message-ID: <20020814145748.07534.00000399@mb-ba.aol.com>
Source record: 136850

Hi,

Am looking for information on supergain monopoles.

I have Bob Haviland's (very nice) article; instead I am looking for published techniques to get a small (less than 1/15 wave) omni-azimuthal monopole to have gain over a quarter wave. (I know that a 1/8 wave, for example, is 'supergaining'; I am looking for known techniques that have been used beyond merely shortening to meet the definition of 'supergaining'.)

I know about bandwidth/impedance issues; mutual coupling; yadayada:-)

I also know how to make a Yagi-Uda supergain. That's not the issue here:-)

Basically I am looking for published techniques to get a short monopole to be gain-ful. My literature search turned up nothing.

E-mail reply is fine.

Thanks,
Chip N1IR

Which is why 106.06 V added in phase with 35.34 V equals 141.4 V for which the total power is 133.3 W in a 150 transmission line. It appears that Cecil does not like to apply superposition to the "fields" themselves (V and I) because the associated powers don't add up correctly. Superposition of power does not work because of the "loss" of the vector information "contained" within the fields themselves. Dr. L. J. Chu, summarized it nicely in the text, Electromagnetic Energy Transmission and Radiation, "it is rare that the powers produced by two separate causes acting individually upon even a linear system can simply be added algebraically to determine the total power when both causes act together." Another fine reference on the subject is Chu's other text Electromagnetic Fields, Energy and Forces.

Cecil,
Uh, don't you think you should run that by a reputable physicist, somewhere?
Or,
better yet, think it through yourself, make a mathematical model, and then
describe
an experiment that anyone can do that supports your model. If you don't take
extraordinary steps to prove the above you run the danger of being labelled a
crackpot, and then no one will listen to anything you say.

Ken,

Be sure you have an external lowpass filter on the HF rig, and it might work OK. Might also cure your TVI. Aug QSL tested LPFs. There were only two that looked any good. One was the Bencher, don't remember the other one. If you don't care about 10 m, any of them would be OK. If it still won't work, you also neeed a high pass filter on the VHF antenna. Since the filters would go in the shack, try it first as is.

You reject everything that proves that Steve has not only violated the conservation of energy principle but has also violated the superposition principle?

> Show us a citation to the application of this novel explanation you
> offer for what you found in your IEEE dictionary.

Egads Richard, are you saying the effects of superposition are irreversible? If so, you and Steve have jointly discovered perpetual motion.

From Johnson: "The principle of Superposition: If a number of electrical sources exist in a linear network, the resulting current *OR* voltage in any part of the system is equal to the sum of the currents *OR* voltages that would be caused by each source acting separately." Note the emphasis on '*OR*' is mine but relevant in the extreme.

Please note that it does NOT say: ... the resulting current
AND voltage in any part of the system is equal to the sum of the currents
AND voltages that would be caused by each source acting separately.

You have your choice of putting the voltages in parallel *OR* putting the currents in series. You are not allowed to do both at the same time.

Steve is adding the voltages AND currents at the same time. That is a violation of the principle of superposition. I got to wondering why the superposition principle allowed violation of the conservation of energy principle. Turns out, it doesn't.

Source record: 136858

Or, as you know and as I mentioned in a posting a short while ago, if P1 = V1 * I1 and P2 = V2 * I2, then the power in the two superimposed voltage and current waves (V1 + V2) * (I1 * I2) isn't equal to P1 + P2. That's simple algebra.

Hi Cecil,

"Network Analysis," Van Valkenburg
"Introductory Circuit Analysis," Pearson & Maler
"Electromagnetics," Kraus
"Fields and Waves in Communication Electronics," Ramo et al.
"The Theory of the Electromagnetic Field," Cook

Are fine by me. They ALL speak directly to the matter. I presume you
have at least one title to offer of your own?

But Cecil, the quote from the IEEE Dictionary doesn't support what you said about superposition. You said:

"The Superposition Theorem
states that energy waves can be superposed at one end and de-superposed (decomposed) at the other end of, for instance, a transmission line."

Your IEEE Dictionary quote says:

"From the IEEE Dictionary: "superposition theorem - States that the current that flows in a linear network distributed in any manner whatsoever throughout the network is the sum of the component currents at the first point." The same holds true for voltages."

These aren't the same. If you want anyone to take your "quiz" seriously, you've got to support what you said the superposition theorem states. The IEEE Dictionary citation doesn't.

Steve, you left out that the current associated with the 106.066 volts is 0.707 amps (75 watts into 150 ohms). The current associated with the 35.355 volts is 0.236 amps (8.33 watts into 150 ohms). The current associated with the 133.33 volts is 0.943 amps (133.33 watts into 150 ohms). You are not only adding the voltages, you are AT THE SAME TIME adding the currents. That is a violation of the superposition principle and leads directly to your erroneous results.

106.9066 volts + 35.355 volts = 141.45 volts
0.707 amps + 0.236 amps = 0.943 amps

Adding the voltages while at the same time adding the currents is a violation of the superposition principle. You are only allowed to add the voltages *OR* add the currents, not both at the same time. Adding both voltages and currents at the same time violates both the superposition principle and the conservation of energy principle. I've been wondering why the superposition principle allowed you to violate the conservation of energy principle. Turns out it doesn't and you are using it incorrectly. That makes most of what you wrote for QEX invalid.

Reference Johnson: page 244 (I found my book, now I'm dangerous :-)
Reference IEEE Dictionary: definition of Superposition Principle

See my other posting on the subject. You are in violation of the superposition
principle which states (indirectly) that you are not allowed to add the voltages
and the currents at the same time. You are allowed to add the voltages OR add
the currents but not both at the same time. That makes most of what you wrote
for QEX invalid including your power arguments with Walter Maxwell.

Einstein was labeled a crackpot at first, Tom. I have a physics minor to go
with my EE degree. Maybe you can answer the question for me. If 50 joules
per second of wave cancellation (that's the definition of destructive interference)
occurs, where does the 50 joules/sec go? If there are only two directions for it
to go (in a transmission line) and it's not going one direction, in which direction
is it going?

Assuming we are talking about average power, Roy, where do those extra (or lacking_ joules/sec go (come from)? The only way for average energy in two summed waves not to add up is to have reflected energy going the other way as an effect of the superposition process.

It is my understanding of the superposition principle as presented by Johnson, that the voltages AND the currents cannot be summed at the same time. Johnson says voltages OR currents not voltages AND currents.

Do any of your references say you can add two voltages AND two currents
at the same time when superposing waves? Johnson doesn't.

Johnson said that "the resulting current or voltage in any part of the
system is equal to the sum of the currents or voltages that would be caused
by each source acting alone." I don't interpret the use of the word "or" to
mean that either the voltage OR the currents superimpose but NOT both.

I would suggest you run a few simple circuit analyses without considering
the transmission line problem we have been discussing. Here's one.

```
+ _________ 50 ohm R _________+
100 V 200 V
- _________________________-
```

"+" reference direction for V and I ===>

Total solution:

Vtotal across R = +100 V - 200 V = -100 V
I across R = -2 A (-100/50), means net current flow towards 100 V source.

Superposition solution at R

with 100 V source. V = +100 V and I = +2 A

with 200 V source. V=-200 V and I = -4 A

Superimpose both V and I. Vtotal = +100 + -200 = -100V. Itotal = +2 + -4
= -2A

By the way, Johnson himself superimposes both voltage and current in this
transmission line analysis in section 4.2, pages 98 - 101. Work through
that derivation of the steady state and it will be obvious to you.

>
>Reference Johnson: page 244 (I found my book, now I'm dangerous :-)

What do you think "distributed in any manner" means? "Distributed in
any manner" includes reconstruction of the original waves.

This information comes from the chart on the instruction sheet that came
with my Isopole.

For 146 MHz. the *top* of the lower cone should be 50 inches from the top of
the mast before you mount the upper element.

The *bottom* of the lower cone should be 75.5 inches from the top of the
mast.

The *top* of the upper element should be 100 inches from the *bottom* of the
upper cone.

It was an excellent antenna until the sun and smog weakened the insulator to
the point that it crumbled and the upper element got blown off in a wind
storm.

I hope this helps.

Who's talking about average power? And what does average power have to
do with travelling waves and superposition?

As for voltages and currents, the voltage at any point along a
transmission line is the vector sum of the forward travelling voltage
wave and the reverse travelling voltage wave at that point. The current
at any point is the vector sum of the forward and reverse travelling
current waves at that point. Any "principle" you invoke to prove
whatever it is you're trying to prove had better produce that result.
Otherwise, it's either incorrect or misapplied -- or both.

Roy Lewallen, W7EL

But Steve, you have increased the power input to the system from 200 watts to 800 watts. Are you saying a 100 watt ham transmitter magically starts putting out 400 watts because your theory demands it? A matched 100w ham radio transmitter is limited to 70.7v at 1.414a putting out 100w into 50 ohms. There just isn't any more voltage, current, or power available to the system. Where does the extra power demanded by your theory come from?

> By the way, Johnson himself superimposes both voltage and current in this
> transmission line analysis in section 4.2, pages 98 - 101. Work through
> that derivation of the steady state and it will be obvious to you.

If the sum of his total powers add up to the total power in the system, then this example is nothing like yours and is therefore irrelevant.
Does Johnson's total power add up to more power than exists in the system?
Where does Johnson say that 75 watts plus 8.33 watts equals 133.33 watts?
Section number? Page number?

> at the same time when superposing waves? Johnson doesn't.

In Kraus' _Electromagnetics_, p. 430, given an incident wave V0, I0 and reflected wave V1, I1 (all vector quantities):

"The resultant voltage V at a point on the line is equal to the sum of the voltages V0 and V1 at the point. That is, V = V0 + V1. . . The resultant current I at a point on the line is equal to the sum of the currents I0 and I1 at the point. That is, I = I0 + I1."

Seems pretty clear to me. You'll also find this implicit in any equations dealing with waves on transmission lines, for example the ones in _Reference Data for Radio Engineers_. Those equations are all self-consistent and lead to verifiable results.

If whatever it is you're trying to prove depends on this not being true, then the conjecture is false and you don't need to waste any more time on it.

> many DX'ers. It is a "hobby" and the UK has it nailed 100% correctly.

To me Amateur Radio is a hobby, but to the FCC it is listed as a service, just as broadcast radio. I chase severe storms and work the weather nets which is providing a service, but to me it's still a hobby as I do it for fun. (I've also seen 5 tornados) I don't care if the individual spends time on CW, digital, TV, shooting the breeze, better known as BSing, or just listening. I don't care if they can copy 40 WPM, or just recognize that afful sound is CW. However, I will confess to setting the rig out in the shop to W1AW and listening to high speed code practice while building an airplane.

The ones in here are set up with the computers for storm chasing, logging, and DXing.

However if you take the word Amateur which is derived from Latin meaning one who does something for the love of doing it and add a Noun such as Radio, then it becomes one who does radio for the love of doing it. (rough translation)

As long as the government keeps treating us as a service we are in a far better position to counter (protect our frequencies from) other groups who would like the frequencies for their own. I would not like to see the word hobby replace the word service as here in the states it would cost us dearly.

Calling the Amateur Radio Service a Hobby would set a dangerous precident in protecting our frequencies at a time when great strides are being made to protect our ability to erect antennas and stations.

BTW, the antenna system here was put up entirely by hand with me doing "all" the climbing. The only place machinery was used was in digging the guy anchor holes and setting the 300# plus guy anchors in those holes. And, yes they did deliver the concrete with a truck. <:-))
http://www.rogerhalstead.com/tower.htm Even with most of the pictures being small links, the page takes a while to load. There's a lot there.

Even though I did all the climbing for erecting the tower and antennas (at my age), my wife put her foot down and said no more climbing for the younger guys. Besides it's time I can devote to building that 335 MPH aerobatic

hotrod. <:-)) Yes, there is a page for it too.

BTW, I spend very little time on the air. Too many fun things to do. (and not enough money)

Didn't see any reply to your query.

To measure gain, you need to first take a 1/4 wave antenna in the exact
same location, and measure the field strength in various locations,
transmitting with the same power.
Do this with both antennas, remembering that all factors must be the same
for true results.
Also, one can test the incoming signal by receiving a signal that is the
same.
You may find very little, if any, difference between the brass and copper
antennas.

>

If you have a 12 V battery across a 1 ohm resistor you get 12 A of current and you get 144 W of power in the resistor. That does not mean that the battery is limited to 144 W output. It is not a 144 W limited power source. Add another 12 V battery in series you now have a 24 V (12 V + 12 V = 24 V) source producing 24 A of current (12 A + 12 A = 24A) and you have 576 W of power in the same resistor. Power superposition does not work. The total power in the resistor is not 144 W + 144 W. This is an accepted fact. This does not violate the law of conservation of energy. Superposition of V and I works fine. There is no need to explain where the "extra" power came from.

Read "Electromagnetic Energy Transmission and Radiation" by Chu. He explains and states it explicitly "it is rare that the powers produced by two separate causes acting individually upon even a linear system can simply be added algebraically to determine the total power when both causes act together." Another fine reference on the subject is Chu's other text electromagnetic Fields, Energy and Forces.

Cecil, this will be my last response to you. Stop with the two 100 W transmitters. That's a diversion to our discussion. I never said once that you could connect two 100 W transmitters and get 400 W total.

In our examples, you need to stop thinking about power superposition and work with voltages and currents. In the forward direction in the transmission line superposition of V and I always works and the total power is always right. There is no need of explaining superposition principles beyond this.

Be very careful in using anti-seize compounds on antennas. Many contain
Nickel, which is one of the metals which is known to be non-linear when
current is passed through it, producing intermodulation.

The 75w + 8.33w = 133.33w in Steve's energy equation are average powers.
75w of average power makes it past the 50/150 ohm junction.
8.33w of average power is re-reflected
133.33w of average power is the forward power on the 150 ohm line.

Those results are produced exactly in my email to Doug Smith. In addition,
all the energy is consistent with the conservation of energy principle.

My complete voltage equation

106.066v + 35.355v + 35.355v - 35.355v = 141.4v

reduces to Steve's equation

106.066v + 35.355v = 141.4v

but since I have all the voltage components, my energy equation balances

75w + 8.33w + 25w + 25w = 133.33w

where Steve's energy equation is ridiculous and clearly violates the
conservation of energy principle.

75w + 8.33w = 133.33w

Sorry, I had a brain fart. But does it say there is more energy in the
sum of the two waves than there the sum of the individual waves.

I cannot believe you guys are allowing Steve to get away with getting
more energy out of the sum of the two waves than the two waves contain
individually. What is the reference for that claim?

> If whatever it is you're trying to prove depends on this not being true,

It was a brain fart, Roy. I superpose voltages and currents at the same
time on my phasor diagram.

You are right.
You want to provide conductivity, anti-seize, prevention of corrosion, and
prevention of any non-linear conductivity (diode effect).
Stay away from Nickle in this application.

A ham transmitter is NOT a battery. A 100w matched ham transmitter can deliver 70.7v at 1.414a into 50 ohms. That's all there is, Steve. There ain't no more. Where do you get a ham transmitter that acts like a battery? My IC-750pro sure doesn't.

> Power superposition does not work.

Nobody has even remotely tried to superpose power, Steve. That's just your attempt at obfuscation. Everything I have said about power is based on the conservation of energy principle which you violate willy-nilly.

> This is an accepted fact. This
> does not violate the law of conservation of energy. Superposition of V and

> from.

Your battery example does NOT even remotely resemble a 100w matched ham transmitter outputting 70.7v at 1.414a into 50 ohms. In your battery example, whatever current is needed is available. That is NOT true of a matched ham transmitter putting out 100w into a 50 ohm load. The battery has all the extra energy you might need. The ham transmitter does not.

A ham transmitter is more like a current-limited battery. So here's your new example. The 12v battery is current-limited to one amp. We put a 12 ohm resistor across it and the ammeter reads one amp. We put another 12 ohm resistor in parallel with the first one. What does the ammeter read now? This is the situation we face with a ham transmitter.

> Cecil, this will be my last response to you. Stop with the two 100 W
> transmitters. That's a diversion to our discussion.

Translation: I cannot answer those embarrassing questions. If I can get 133.33 watts out of adding 75 watt and 8.33 watt waves, why can't I do the same thing with two ham transmitters? Where does the extra power come from in the addition of the waves that is not available in the ham transmitters?

> I never said once that
> you could connect two 100 W transmitters and get 400 W total.

But you have said you can connect (superpose) two 100w waves to
get 400w total. If each of two waves contains 100w and you combine
them, how do you possibly get 400w out of them. The transmitter
is only supplying 100v at 2a into a 50 ohm load. Where does the
extra 200w come from?

> In our examples, you need to stop thinking about power superposition and
> work with voltages and currents.

You need to stop accusing me of something I wouldn't even consider doing.
Have you stopped beating your wife?

Steve, if two pure sine waves can be superposed into a single wave, then that
single wave must be able to be decomposed into the original two sine wave
components. Please tell us how to decompose a 133.3w wave into two waves of
75w and 8.33w.

I'm still not convinced that dx/dt + dx/dt is equivalent to x + x, however,
let
me make two points: 1. You're not Einstein. 2. People had to believe Einstein
was right when his theory successfully predicted the results of verifiable
experiments. If you can come up with some experiments that will satisfy
your scientific peers, hey! I'll be the first to congratulate you. Be prepared
for

some scepticism, however.

It's a good quality grease in appropriate applications. Assuming the
context involves "antenna grease" the much better idea is graden
variety front wheel bearing grease which is specifically designed to
resist being washed out by rain, etc. If there is a lithium-based
grease compounded as a wheel bearing grease so much the better.

I'm well aware that the tests must be made under the exact same conditions.
Same location, elevation, power and so on.
A lot of hype going on about some antenna designs.

I did some testing, years ago, of 11 meter antennas (mobile whips).
Put my car on front of the shop, and had a combination test unit in the
window.
Test unit, Lafayette, had field strength meter, and signal generator in it.
By changing only the antenna, I tested both field strength and received
signal.
Antennas tested were a full 1/4 wave glass whip, a Francis (supposed 3/4
wave, 7'), and several other shortened whips.
Needless to say, the full length whip beat all the others in both TX and
RX.
I'm well aware that any shortened antenna simply cannot perform as well as
a longer antenna that is properly matched and fed with the same basic cable

For the record, I held a commercial 2nd class radiotelephone license at
that time.

Dave,
Have not seen many designs for more than a 3 or 4 element quad, but here is a suggestion.
Take the 4 element, and add more directors.
make each new director a bit smaller in dimension as the preceding. Smaller towards the front.
Some may say to increase the spacing as you extend the unit.
This, as I understand, makes it more directive, and rejects more off the sides.
And I saw one design that added a second reflector on the rear. Increases front to back rejection ratio.
A bit of a search on the internet should show the basic designs.
Don't forget, the longer the boom, the more it needs added support.
While PVC is cheap, it has a limited life.
Sunlight deteriorates it. Heat deteriorates it.
It's advantage is that it is non conductive and adds no reactance of any kind to the elements.

Greg -

I have been assigned the job of getting Ed Juge W5EJ any information or documents that he needs to install (and receive building permits) for our Hy-Gain Hy-Tower Vertical antenna product. (The core is actually a Rohn tower product). This data contains all specifications such as, windloading, stress testing, materials used, tolerances, etc.

I do not know why we (MFJ) have not included this data with the Hy-Tower product when reintroduced, but we get a copy to Ed. I am talking to management (MFJ) to see if we can get this data on our MFJ / Hy-Gain website in PDF format ASAP.

Thanks,

Jim Shurden

Tdonaly wrote:
> I'm still not convinced that dx/dt + dx/dt is equivalent to x + x, however,

The fact that dx/dt + dx/dt is not equal to x + x supports my side of
the argument, Tom. I thought my transformer example would shed some
light on why 75w + 8.33w is not equal to 133.33w.

Transformer primary input #1, 106.066v at 0.707a
Transformer primary input #2, 35.355v at 0.236a
Transformer output into 50 ohms, 64.55v at 1.67a

Whoops, why isn't it the same as Steve's result of adding those same
two waves? Because Steve is ignoring 50 watts of power sourced from
the interference pattern.

Transformer primary input #1, 106.066v at 0.707a (75 watts)
Transformer primary input #2, 35.355v at 0.236a (8.33 watts)
Transformer primary input #3, 86.6v at 0.577a (50 watts)
Transformer output into 50 ohms, 141.4v at 0.943a (133.33 watts)

What do you know. These results match Steve's (except for that
pesky extra 50 watts on input #3)

> let me make two points: 1. You're not Einstein.

I've got approximately the same equipment as Einstein. Want to know
why the Red Shift is not all Doppler Effect?

I forgot to ask. Doesn't anyone find it strange that Steve's superposing
of two waves is 160% efficient?

100 x 133.33w/(75w+8.33w) = 160%

Perhaps. But who says you can sum the powers in the waves to get the total power? You can't. The fields, voltages, and currents superpose, *but the powers of the individual waves don't*. Here's a challenge for you. Find a single reference, anywhere, that talks of the superposition of power waves, or the power in waves.

> I cannot believe you guys are allowing Steve to get away with getting
> more energy out of the sum of the two waves than the two waves contain
> individually. What is the reference for that claim?

What's the justification for your assuming that you can simply add the powers in the individual waves to get the total power? You can't, as simple algebra shows. This is not D.C., and the waves are moving through space. All that we have to guarantee at the end of the day is that, if the line is lossless, our calculations had better show that the the power out equals the power in. Conventional transmission line formulas do that just fine.

>. . .

>>If whatever it is you're trying to prove depends on this not being true,
>>then the conjecture is false and you don't need to waste any more time
>>on it.
>
>
> It was a brain fart, Roy. I superpose voltages and currents at the same
> time on my phasor diagram.

By the way, when you add up voltages and currents, be careful how you define the direction of current. If the positive direction is defined as being in the direction of travel, then the superposition of a forward travelling wave with voltage and current V1, I1 at a given point and reverse travelling wave V2, I2 at the same point is V1 + V2, I1 - I2.

Do your calculations with the voltage and current waves. When you're done, you can calculate the power from the source and into the load, and you'll get the right answer. If you declare that the power in the forward wave plus the power in the reverse wave have to add up to the power in the superimposed V and I waves, you'll get the wrong answer more often than not.

Originally, heath suggested transformer oil, with mineral oil as a
substitute.
Lower rating with mineral oil.
In fact, it showed the rating curves for both on the side of the can.

I'm using that RS discone antenna.
Change I made is using a 6 meter ham Stick on a bayonet mount.
Worked well enough last night with an opening to Montana.
And the two meter and up still has nice low SWR...
Will work for 10 meters by changing whip.
Mine is offset slightly, till I can find or make a better adapter.
I love experimenting.

Ham Stick is easier to tune, and I can just reach the antenna to change
whips.
YMMV

The RS discone is not a gain antenna, but is broad banded as all heck on 2 meters and up.
Roughly equivalent to a 1/4 wave ground plane (with drooping radials) on all but 6 meters.
I find you can, by using an adapter (may need to make one) use a 3/8-24 whip for six, or even ten meters on this item.
No problems with radials yet, but only a few months so far...

It's real strength is in it's makeup that stops the galvanic effect between two dissimiliar metals. It it this galvanic effect that leads to quite a bit of corrosion. So for battery posts (lead post/brass clamp) it is ideal. Your ground rod clamp is also usually a different metal than the actual ground rod so again, it would be useful. In household wiring, it is a must between aluminum conductors and copper terminals. Without the compound, the junction can become red hot and burn the house down. Aluminum wiring was the cause of many fires and they almost pulled it from the market until they figured the paste would solve the problem. Now it is codified in the NEC.

I work in the alarm industry and deal with this type of problem all
the time and the answer is simple. Change the length of the loop for
the zone that is going into alarm when your tuning up. The easiest
method is to break the loop near the control add say 75 feet of wire
to the loop. What's happening is the wire length of the alarm loop is
somewhere near a multiple of 1/4 wave on 20 meters. You may have to
experiment with some different lengths but at some point you should
find a length that will work. Take all those nasty toroids and crap
and throw them in the trash, they are worthless for this kind of
problem. You also should be very careful because you are feeding RF
into your alarm panel and I have seen plenty of controls fried from
high amounts of RF induced through zone protection loops. The other
problem you may be having is that your antenna is a vertical and this
wire between floors is mostly a vertical run. This can be a major
problem especially if the radiated RF is within say 75 feet of the
loop wiring. Another solution is to move the vertical farther away
from the house or go to horizontal antennas. Too much messing around
in the control and you will be replacing it and they are NOT cheap.

Source record: 136720

Cecil,

Actually, "Steve's model" is not nearly as efficient as yours.

The mysterious waves that carry the missing 50 watts are stated to be traveling in the same (forward) direction on the 150 ohm section of line. They have the same magnitudes of both voltages and currents. However, there is a phase reversal on one wave so that the waves exactly cancel (or annihilate, or destructively interfere, or any other such description you like) along the entire length of the 150 ohm line. In other words, these supplemental waves simply to not exist; they are gone. They certainly are not "observable", meaning they cannot be *measured*. (It is not fair to add circulators or other non-linear devices, since the circuit is significantly changed by the insertion of such devices. Any measurements would be meaningless for the issue at hand.)

So in effect we now have the CAM model in which 50 watts is somehow transported with no carrier at all. This is extraordinarily efficient. Why not just go for a megawatt? It should transport just fine over 30 gauge twinlead since there is no current. No voltage either, so the wire does not even need to be insulated.

It is silly to argue that somehow the waves still exist and can later be "reconstructed". This is not the same as the example you gave some time ago about waves reflecting off the beach. Your 50 W waves are not just passing by; they completely cancel. In classical physics you cannot create light and anti-light out of darkness.

You set up an ideal system with no losses, completely linear, no dispersion, zero-width spectrum, etc., etc. What "action at a distance" allows the purported waves to know how to reconstruct when their essential power balancing task is done?

There are many times in math and physics when it is convenient to add auxiliary functions to aid in the analytic solution of a problem. However, one must be careful about ascribing physical reality to these auxiliaries unless the physical characteristics can actually be observed in some manner.

A model is most useful when it correctly describes physical reality for any input conditions within the range allowed for that model. In this regard there is no difference between Steve's model, your model, or W2DU's model. You can input any appropriate physical conditions into any of these models, and the physical output is the same.

What goes on inside the model is only an issue for philosophers, not for technologists.

73,
Gene, W4SZ

(V + V*Gamma)(I - I*Gamma) = VI - VI*Gamma^2. This is a special case.

Now try this: (V1 + V2)(I1 + I2). Also, if V1 = V2 = V and I1 = I2 = I, P1 =
P2 = P. (2V)(2I) =
4VI, so P + P = 4P. Many people have a hard time believing 1 + 1 = 4,
especially Cecil, but
when you're dealing with adding powers you have to get used to it.

That's not true, Gene. That 50 watts is carried by the forward wave.
Where do you think the light goes in a non-reflective picture glass?
It suffers destructive interference in the coating and goes the other
way. Light is an EM wave. RF waves are EM waves. Destructive interference
happens with light and RF waves. There's just usually not enough energy
in light to burn your fingers. 50 watts is just too much to sweep under
the rug.

> It is silly to argue that somehow the waves still exist and can later be
> "reconstructed". This is not the same as the example you gave some time
> ago about waves reflecting off the beach. Your 50 W waves are not just
> passing by; they completely cancel.

They completely cancel toward the source through constructive interference.
The energy in the canceled wave heads the only other direction possible.
It joins the forward wave in the 150 ohm line. You somehow have it backwards.
The two waves that are canceled are flowing toward the source. They only
flow an infinitesimal distance before they are canceled.

Water waves can completely cancel also. It's just more difficult to control.

> You set up an ideal system with no losses, completely linear, no
> dispersion, zero-width spectrum, etc., etc. What "action at a distance"
> allows the purported waves to know how to reconstruct when their
> essential power balancing task is done?

All waves moving in one direction superpose. All waves moving in the other
direction superpose. After superposition, we are left only with our old
friends, forward power and reflected power.

> What goes on inside the model is only an issue for philosophers, not for
> technologists.

What goes on at an impedance discontinuity is only an issue for philosophers?
Maybe your and my existence is only an issue for philosophers.

Here's my quiz (don't worry, it's trivial):

Take two '100 watt transmitters' and phase lock them out-of-phase. Connect the two transmitter outputs directly using a *very very short* jumper coaxial cable. How much power is in the cable ? In theory, according to my assumptions, net V is zero due to cancellation .: P is zero. Hmmm...
Where did the 200 watts go?

Because space itself is expanding. That's a little different from things moving apart. With an expanding space, things can stand still and get farther apart. The same thing that is causing the expansion of space is causing seconds to get shorter which also looks like a Red Shift to people who are measuring cycles/second.

Hi Cecil,

No, coating on lenses work just like any other tuner, they shift the phase such that AFTER the transmission THROUGH the lens, the combination of waves cancel. In fact the coating provides a resonant chamber that re-reflects to accomplish this phase shift. Basically it employs the same mechanics that serve the relationship between Director and Reflector in a yagi.

>There's just usually not enough energy
>in light to burn your fingers.

has absolutely nothing to do with anything.

>The two waves that are canceled are flowing toward the source.

You've been staring into the sun too long with your special coated sunglass lenses.

How is that different from what I said? Cancellation is destructive
interference. The resonant chamber of coating is "in" the coating.

Tom, KA6RUH wrote:
"Many people have a hard time believing 1+1=4----."

Transmission lines are conduits for work or energy units
(joules=wattseconds).

You can`t get more energy out of the conduit than you put in. Nor, can
you get it out any faster than you put it in because there is too little
storage to allow store and forward of energy. So, there is no energy
bunching anywhere in the conduit. A power meter shows a constant power
throughout the transmission line. 1+1=4 in this case is crazy.

Bert,
I'm not sure I understand your description of
how the ladder-line runs. The feed line's route,
along with it's length can affect the whole antenna
system's impedance matching requirements and so the
antenna system's performance. So, the quick and
dirty answer is that yes, it will affect how well
your antenna system works. I can't say if the change
will be for the better or worse 'cuz I just don't
understand your description (it's late, and any other
applicable excuses).

I want to connect my 450 ohm ladderline to my Yaesu FT-757GX which has a FC-757AT automatic antenna tuner. The tuner has only a 50 ohm coax connection. I don't have a balun trans. but am looking for one. (I live in a very small community.)

I also have an MFJ Versa Tuner II which does accept the ladderline.

Would there be too much radiation in my shack if I use the MFJ for the time being?

Can I just replace the balanced line with coax?

What would be my best options?

When/if I get the balun, how long should my coax be?

Thanx!

J. Harvey wrote:
"Take two "100 watt transmitters" and phase lock them out-of-phase. Connect the two transmitter outputs directly using a very very short jumper coaxial cable."

This connection and phasing is equivalent in many ways to a d-c circuit using two batteries in series. Without load resistance, the voltage generated by each transmitter is effectively driving all the current it can into its own internal resistance, or 100 watts worth.

Total power is 200 watts generated and dissipated and equally divided between identical transmitters. Current in the cable connecting the transmitters is the same as either transmitter produces at 100 watts because that is their maximum production and they are effectively connected in series.

This example assumes a current constrained transmitter where a matched load causes 100 watts transmitter dissipation. In other words, when the transmitter delivers 100 watts to an external load it normally dissipates 100 watts internally.

Best regards, Richard Harrison, KB5WZI

Easiest way to make a 1/2 wave on 20m is to use a single piece 32 ft
radiator and a single turn loop and cap at the base. IE: ringo.. You
would want a single turn loop of appx 18 or so inches diameter. The
cap would be appx 100 pf or so, and can be made from coax. MK

2998. motor driven vacuum variable question

I have one of those modularized vertical pull 0-3000pfd variable capacitors that have a 28vdc motor drive. It has limit/stop/reversing circuits that terminate in a small D ring 15 pin socket. Looks like it could have been made by Collins. The vacuum variable is a Jennings.

A few years back, some nice ham sent me a circuit diagram of this thing, and I somehow (foolishly?) lost it.

If anyone has the wiring diagram, I'd sure like to get a copy. All help

May I ask, why don't you just try it? You can learn a heck of a lot more from trying something than asking opinions on a newsgroup. To answer your question, a tuner is a tuner some work better than others, your versa tuner should work just fine. For that matter, connect a short piece of coax directly to the ladder line and use the other tuner. Is it perfect? Nope! but it will darn sure work, the tuner will make up for the mismatch and do you care if the mismatch is because of non resonance, impedance, or bird crap on the antenna?

A big ol' toroid with several turns of RG-6 right before it goes into the TV should do a lot for you.

A buddy of mine had a real TVI problem. The cable type high pass filters didn't help one bit. What worked for him was a 75-300 ohm transformer, a 300 ohm HPF, then another 300-75 ohm transformer. The problem is that the RF simply flows down the shield of the coax, right around the 75 ohm HPF, and into the TV. By going to 300 ohm first, the RF on the shield is converted into simple "common mode" noise, which the 300 ohm HPF easily got rid of.

The subtraction is misleadingly simple... and I'm afraid you have been misled.

The theory is explained in 'Reflections 1', and it depends only on superposition of forward and reverse voltage and current waves - *not* superposition of power.

> in any way?

Since you are running a balanced antenna, the feedline should not be radiating (i.e., the currents on each side are equal). So, from that respect, it should not make a difference.

However, getting the ladder line away from the roof edge should improve the performance of your system. It may not be detectable, but there is an impedance "bump" where the ladder line gets close to the roof edge, especially if there is metal there (which there normally is).

Also, raising the feedpoint of your antenna should also make a slight improvement.

Sorry, but that's wishful thinking. The reality is exactly the opposite:
"If you want to run a balanced system, the feedline must be prevented
from radiating (i.e., *you* must make sure that the currents on each
side are equal)."

As well as carrying differential-mode "balanced" current, parallel-line
will quite happily support common-mode "antenna" currents at the same
time. In other words, so-called "balanced" feedline is only *capable* of
being balanced - nothing more.

It's up to the user to *make* it balanced, mainly by using the most
symmetrical layout possible.

Your antennas could have experienced higher wind speeds than recorded at the weather station.

One would hope that you wouldn't experience damage to the antennas unless the winds were strong enough to damage some other substantial structures in the area. So, if your two antennas were the only things damaged and no one lost roof tiles, gutters, tv antennas, satellite dishes, etc, the designs may be a bit weak.

MFJ's online specs don't include a wind survival rating.

I note that Cushcraft's online specs have wind survival ratings for those "commercial" products that I sampled, but not for any of the "amateur" products that I looked at.

Perhaps that indicates what type of buyers we tend to be! We seem to expect wind survival ratings for towers, but not the antennas.

Nice that MFJ replaced the parts. How often will you experience winds like that... the weather station reports were not especially high velocity?

Owen

Thank you Richard. I am not aware of any other side, FYI. Happy to dig out anything from Laporte for you.

I have the info I need (I had requested e-mail). Thanks to all for looking at my request.

Does anybody has a practical experience in a J for UHF using Twin Lead.

I have experimented wiht 2m version and works very well. But i can not
adjust swr for UHF

Mesures:
Long part: 45.5 Cms
Short part: 15 Cms
Feeding point: 1.3 Cms from the end
End shorcircuited.

Any help will be wellcome.

Thanks
EB5FLS
Op. Pedro

Ian, G3SEK wrote:
"The subtraction is misleadingly simple."

There are two directions of transmission in a coax, toward the load and away from the load.

Bird`s slug responds to in-phase power in each direction, one direction at a time. Power flowing away from the load is a reflection. Power flowing toward the load contains power accepted by the load plus the reflection. Subtract the reflection from the total forward power and you have the power delivered to the load.

As the transmitter has only to deliver energy at the rate it`s taken by the load, the power delivered by the transmitter is the same power taken by the load, assuming insignificant loss in the coax.

These power measurements may be made anywhere along the length of the coax and the power indications are the same at any place unless loss is significant. If the coax is lossy, the Bird can be used to measure power into the cable and out of the cable and the difference is the cable loss.

This is simple and it works.

Best regards, Richard Harrison, KB5WZI

There is some average energy "stored" dynamically in the forward wave
and reflected wave and it must remain constant during steady-state.

But you are right. During steady-state conditions, we cannot get more
average power out of the transmission line than we put in.

Richard, I didn't say in my posting above in which direction it cancels.
It obviously cancels in the direction of the viewer. That's the entire
purpose of the reflectionless glass - to cancel the reflections in the
direction of the viewer.

Let me expand my above statement to include direction. "It suffers
destructive interference in the coating and goes the other way"
toward the picture instead of toward the viewer. I thought that
would be self evident.

>velocity?

You are correct about towers suviving.. as a matter of fact, MFJ stated that if my two antennas lasted a year, that's good... apparently they don't expect their antennas to last more than a year. They've offered to replace radials, but not much else. They don't want to replace the whole antenna. The winds that night were one of those storms you might get once a year... very severe storms, but a rare occurance. We had storms like that about a year ago and the antennas survived fine at my old QTH, only a couple miles northeast of my current QTH.

The coax fills at almost 125,000 miles per second. How many miles of coax do you have? We are measuring energy flows in joules per second. How many joules are stored in a coax in the tiny fraction of a second that elapses in the time it takes to fill the coax?

It isn`t worth mentioning.

I've been using a RS discone for several years and love it for receiving on a wide assortment of bands. I also transmit on 2 meters on the antenna. I've also had the problem with ground plain radials because of the small screw threads working their way loose and falling off and they are easily broken off during handling if you're not careful. Maybe some bonding agent would work holding the radials in. Next time I take the antenna down I'm going to try something like that. My discone is about 5 years old I guess.

"---will 600 watts of HF de-sense the tribander (VHF) on RX---?"

Cross-polarization loss may be only about 20 db. Receiver gain is usually more than 100 db. Simple answer is yes, you will have de-sense unless powerful preselection is used with the receiver and added harmonic suppression may be needed at the h-f transmitter, too.

My experience includes reception of 100 MHz signals at a shortwave broadcasting station. This required moving the corner reflector receiving antennas 1/2-mile from the transmitting plant with the backs of the reflectors facing the plant. These were cross-polarized with the shortwave antennas. The shortwave antennas were also a 1/2 mile or so away in the opposite direction from the plant and the plant was on the back side of their reflectors.

While that's probably true, I'm relatively new at this and don't mind
asking those of you who have more experience. I could probably benefit
more from your experience than my mistakes...and it could be less costly.

That's what I was needing information on. Connecting a 450 ohm line to a
tuner that calls for a 50 ohm coax didn't seem like a good idea...one
that I HAD thought of. I wasn't sure if the tuner would make up for the
difference or not. I appreciate your input.

I'm retired, Bill. I do all of the above plus much more. I use this newsgroup as a learning experience. I have learned a lot. I often toss something out so the newsgroup can, in its collective wisdom, perform the scientific method on it. I recently received a helpful email about superposition.

The superposition theorem states that the system involved must be linear. If the power source is linear, when we superpose 100v at 2a in phase with 100v at 2a, we do indeed get 200v at 4a and the power output of the source has supplied the extra 400 watts needed for the superposition. If the constant voltage power source is current limited to 400w, then the signals cannot be superposed to 200v at 4a. If they are confined to a 50 ohm environment and power limited to 400w, the best possible result of losslessly combining them in phase will be 141.4v at 2.828a. This is what happens with a transformer.

The emailer said that the hole in my argument is that a ham transmitter is not a linear device. Seems that might also be a hole in Steve's argument. If a ham transmitter is not a linear device, then Steve is not allowed to use the superposition theorem on a ham system. But that's what we have all been doing.

A source doesn't have to be linear under all conditions to satisfy the requirements of the superposition theorem. It only has to be linear over the conditions that are encountered in reality. A 100w ham transmitter looking into 50 ohms at the input of an antenna tuner certainly satisfies the linearity requirement. It is putting out a constant 70.7v at a constant 1.414a.

The energy needed for Steve's superposing is indeed supplied by the system. The extra 50 joules/sec required is supplied by the superposing of two complimentary waves whose voltages and currents cancel but whose energy is delivered to another set of superposed waves. I will head over to Texas A&M next week and try to find references for all that I have been asserting. But the aliens assured me that all of this is true.

For 100ft of transmission line, 200w of forward power, and 100w of
reflected power, I calculate it to be 0.0453 joules. :-)

You're absolutely right about the constant power in an ideal transmission line,

Richard, but transmission lines are complicated devices where voltages and currents add and subtract in ways that have to preserve that constant power. Moreover, the voltages and currents themselves are the results of superposition of
reflections (except in the case of a transmission line terminated in its characteristic impedance, of course).
Let's take a simpler case, a resistor. Put one volt across a resistor of your choice.
Calculate the power. Now double the voltage and calculate the power. Here's a simple
example: 1 volt across 1 ohm is 1 amp. Add a volt. 2 volts across 1 ohm is 2 amps. The
power in the first instance is 1v*1amp=1watt. if you add another volt
(1v+1v)(1amp+1amp)=4watts.
So one watt plus one watt = 4watts, which, as you can see is a fact hard to live with, and the reason you should add up your volts and amps _before_ you calculate your power if you don't want to end up making a fool of yourself in public.

Hello all,

I just now latched onto the barking contest between Cecil and Steve on this subject. I haven't read each post, but loaded them onto the hard drive for future review. However, I noted one comment from Cecil that really bothers me, when he said that Steve has proven me wrong concerning total re-reflection at a matching point. Not true. Steve may have persuaded a few that he is correct on this point, but he still has me and many others yet to persuade--lotsa luck.

So let's first discuss virtual open and circuits that achieve the re-reflection, circuits Steve says don't exist. Perhaps my definition of the circuits is in order to ensure the disagreement isn't over terminology. My definition of virtual short and open circuits are those established by wave interference between two rearward-traveling waves generated by two mismatches encountered by a forward traveling wave. By whatever device necessary to achieve it, the two rearward traveling waves are of equal voltage magnitude and of opposite phase (180 degrees), with currents equal and in phase at the matching point. This condition establishes a short circuit to the rearward traveling waves, but Zo to the source waves. Thus the direction of energy in the reflected waves is totally reversed. OTH, some may consider real the circuits I call virtual. My use of virtual is to differentiate from physical short and open circuits. Perhaps my calling these circuits 'virtual' is the problem.

The point overlooked when denying that the short circuit exists is that the voltages and currents in the two rearward-traveling waves represent real power. These voltages and currents at any point on a line, such as at the matching point, can be replaced analytically by two separate generators at that point delivering equal out-of-phase voltages. The result is zero voltage and maximum current--a short circuit. (The current does NOT go to zero.) At the short circuit the electric fields collapse and their energy is transferred into the magnetic field, enlarging it to double its original value, thus the current also doubles at that instant. But the changing magnetic field generates a new electric field equal to the original, but traveling in the opposite direction according to the Poynting theorem. The energies in the reversed electric and magnetic fields now traveling in the forward direction merge with the corresponding fields of the source waves, with the result that the power in the former reflected waves adds to the source power. For emphasis, the energies in the fields merge, not the voltages. Adding the voltages produces absurd answers.

This leads directly to another point where I've been erroneously contradicted. Contrary to Steve, source and reflected voltages do NOT add to establish the forward voltage, and ultimately the forward power. The forward

voltage is determined from the forward power flowing in Zo, which is constant except for attenuation. The reflected voltage alternately adds to and subtracts from the forward voltage to establish the standing wave.

Bert, when the ladderline comes away from the dipole at any other than a 90 degree angle you begin to change it to a unbalance situation, the more the angle the more the unbalance. Radiated RF from the side of the antenna where the feedline runs closest will be induced onto the feedline. Whether or not the effects are serious is best determined by trying it. If thats what you need to do to, go ahead and see how it works out. It probably won't be a problem.

I live in California, Cecil. The power companies do stranger things with
their arithmetic than I could ever imagine.
Watts and watt-hours are two different things. Watts are the rate of
doing work and watt-hours are the total amount of work itself. I would
be delighted to see the power company add powers the way you do;
(1v+1v)(1a+1a)=2w. Unfortunately, the power company doesn't have a
sense of humor.

3026. Tower resrtictions near an airport

Date: 2002-08-15 15:26:02 UTC
From: Jim <yoda581@msn.com>
Message-ID: <ajfrtl$19li$1@feed.centurytel.net>
Source record: 136767

I used to have an address for the rules on tower heights within so many feet of an airport, but I can 't find it now. I tried the faa web site, but got lost in there. I also remember an on-line calculator where I could enter my coordinates and it would tell me how high I could go, I think.

Does anyone have a link to any of this info?

Thanks! & 73

Jim

>Richard, I didn't say in my posting above in which direction it cancels.

Hi Cecil,

Really? Perhaps you should read your own writing:
>They completely cancel toward the source through constructive interference.
>The energy in the canceled wave heads the only other direction possible.

This hardly matches the howler:
>They only
>flow an infinitesimal distance before they are canceled.
which sounds like a "hail mary" characteristic to CYA. Why any
distance at all? Again, another unique attribute of wave mechanics
that has to be invented from whole cloth to support a failed argument.

Sorry Cecil, you not only said it, you underlined it and promoted it
as a new entry in your physix of the cosmos.

Mr. White is right, it is misleadingly simple, and doesn't prove superposition
of
power in any case. There is absolutely no mathematical justification for the
concept of superposition of power, whatsoever. No textbook author would
espouse
it, and no course teach it, because it is fundamentally, and irrevocably wrong.
If
it were true, the superposition theorem of voltages and currents wouldn't work,
and
all network analysis would be little more than a hoax foisted on unsuspecting
EE students by cruel and intellectually dishonest professors.

I am afraid you would be disappointed with the performance with both the
hamstick and a so-called tuner. I know some people turn pale at the thought
of putting a "Big, Ugly" HF antenna on
their cars, but the real "skinny" is You Can Have Pretty, or You Can Have
Performance. Unfortu-nately, on the lower HF bands, the two do not go
together. If you want multi-band and the best
performance, your best bet is a screwdriver (Carolina Cyclone LOL!). If you
are willing to forego
80 and 40, you can do pretty well on 20 meters up with hamsticks (fair) and
maybe even use your
"tuner". It truly depends on what you are willing to sacrifice. With low
frequency HF, there are
no effective shortcuts.

Tom, KA6RUH wrote:
"The power in the first instance is 1v times 1a = 1watt---."

All that math and no mistakes!

Ohm says power is E squared over R. So, if you double the voltage across a resistor, of course you quadruple the power.

One reason the communications industry uses power to express signal levels, the milliwatt is a power, is to avoid impedance related arithmetic.

If you know the power at a point with respect to a milliwatt, it makes no difference if the impedance is 50 ohms, 75 ohms, 300 ohms, 600 ohms or 377 ohms, until you need to determine the voltage or current at that particular point. Otherwise, you may happily add and subtract db`s until you are ready for specific volts and amps.

Best regards, Richard Harrison, KB5WZI

All,
I've been thinking of putting my Kenwwood TS-690 in my car, and have looked at the Hamstick antennas.
I would hate to be limited to only one band, and yet don't want to buy more than one of these (I am on a limited budget).
Since I have an internal antenna tuner in my radio, could I use one of these antennas on different bands? Is it possible to use the 80m antenna, and then still get adequate results on 10, 15, and 20 meters? Or should I just be satisfied with operating on one band?

Thanks for any insight!

That rule doesn't give the whole picture by any means. There are additional regs dependent on proximity and bearing to the various classes of runways.
I went thru the search about a year ago and it was a real maze. Check via FAA sites, not FCC, if you are anywhere close to an airport.

>that's what we have all been doing.

Hi Cecil,

I see you now understand how both sides of an argument are affected if one side is when a common point of intersection fails. This was how you failed with the transformer argument.

It is the system that must be linear, not any particular component as you've allowed:
>A source doesn't have to be linear under all conditions to satisfy
>the requirements of the superposition theorem. It only has to be
>linear over the conditions that are encountered in reality.
Of course, if a non-linear component is a principle of the system, it may impart its non-linearity into the system. I have designed innumerable amplifiers that contained many non-linear elements to only produce a fully linear response. As such, the inclusion of non-linear elements did not impart their characteristic and this was accomplished through the agencies of my design (H.W. Bode instructed this matter 60 years ago).

This is not to say that a ham transmitter, or any transmitter serves to illustrate these issues under discussion - that is, not without sufficient qualification. You took care of that when you offered the use of a laboratory grade source. I have calibrated many of those too, most of them suitable for use as transmitters.

The only problem of the transmitter application is that preconceived notions of what it is and what it can do pollute the discussion with unstated boundaries. This, then, returns us to the duality of the source being linear/non-linear. To this point we arrive by the common boundary condition stating that wave X is thus and wave Y is another. We then combine them and ask what has happened. The unstated tenet (from you Cecil, and embraced by you as a common understanding - another failure of logic) is that the sources will not allow such combining on the terms offered. This is a failure of the model, not the theory.

The original topic concerned waves, not sources. Cecil, you have argued a source limited argument against Steve's wave descriptions. The same goes for your transformer argument that collapsed on just those same terms (and you failed even to notice how). Thus your model revealed a non-linearity to the issue at hand - it did not cope when the wave combined. Bluntly put, any appeal to the source for the action of a wave at a distance must implicate the entire model. Your arguments clearly lean heavily on the source offering some restriction, Steve's argument did not.

Now, when you lean on this as being a common experience - certainly, of course it is; it adds nothing to your argument about waves. You did not offer this restriction originally, in fact you never offered it at all. It is simply a prejudice - not a necessity. Richard Harrison has weighed in with practical correlatives. Even to combining two hefty transmitters and guess what? the powers added according to your prejudices - the practical sources were obviously power limited.

Again, I would point out that Bart's thought example anticipates all these considerations and employs exactly the style of discussion you prefer. Bart's model completely divorces the sources from the mechanics of the waves. Bart's model is clearly superior.

I use an LDG RT-11 tuner and Hustler antennas with my IC-706. I can tune about one band either side of the band the antenna is designed for. For example, I use the 17 meter antenna and tune 15 and 20. I can use the 10 meter one and get 10 and 12. However, 40 and 80 (which is about useless) require the correct antenna. I can't say for sure, but I believe the LDG tuner is a bit better than most internal tuners.

A few posts back Steve referenced Johnson's Pages 98-101, where Steve says the derivation in the steady state shows voltages and currents adding to determine the forward voltage and current.

Unfortunately, Steve misconstrued the purpose of Johnson's derivation, because instead of deriving forward voltage and current it derives the standing wave of voltage and current. Big'a differencia'. I pointed this out to Steve many, many months ago. Didn't take, did it?

Hi Crazy George

You just answered a puzzling antenna problem I had in the past,
without even realizing it. Thanks!

I had used some nickel plated copper to build a small 440 yagi. It
was identical to one I had made of all brass that worked perfectly.
Yet it put out harmonics all over the place and had very little punch.
I took it down and trash canned it, but never knew why it didn't work.
I guess the nickel coating was the culprit.

Rezster,
I'm not familiar with an 'AS-2' antenna, but, if it is simular to the G5RV in that it uses a section of 450 ohm ladder line in impedance matching, then I think you could do away with the coax completely, then run the ladder line to the MFJ tuner (by-pass the Yaesu auto-tuner completely).
Will this mean there would be 'too much' radiation in the shack? I very much doubt it. If you mean RFI from the ladder line coming into the shack, well, that just depends. I use ladder line feed line coming into the shack with no problems. The computer is less than 4 feet from the ladder line and doesn't have a problem with the RF. Others have had problems, though, so I think it's one of those "try it and see" things.
Good luck...
'Doc

Thanks for the info!
I guess the best thing to do is just try it out. It looks like I'll stay away from the 40/80m versions and try something that will give me results on 10/15/20 meters.
I was planning on either mounting the antenna to my rear bumper or possibly the front hood area. It'll be mounted on an older Isuzu trooper, so the ugly factor isn't really a consideration. The real factor was primarily low investment. These antennas seem inexspensive enough to experiment. I just don't want to buy 4 different antennas, when one will do the trick.
Most of my operating has been in the 10/15/20 meter bands.
Thanks once again.

If your theorem doesn`t work, you had better change theorems or find how the theorem is being misapplied. It is silly to argue the Bird wattmeter doesn`t work. It gives good accuracy within its specifications. It is the standard by which other field instruments are judged.

There is no fraud in the Bird`s operation. You may violate civil or criminal laws, but you don`t violate the laws of physics. The Bird is legal.

> persuade--lotsa luck.

In order to prove your point, Walt, you are going to have to prove that
wave cancellation is technically the same thing as re-reflection. That's
a tough argument but let me give it a go.

When a wave of 1 volt at 1 amp in phase at +90 degrees is superposed with
a wave of 1 volt at 1 amp in phase at -30 degrees traveling in the same
direction, the result is a wave of 1 volt at 1 amp in phase at +30 degrees.
Each of these waves has an associated intrinsic energy of one joule/sec. So
has two joules/sec magically transformed to one joule/sec. Nope, there is no
way to superpose those two waves, assuming no other waves exist, without
generating another wave of 1 volt at 1 amp. The superposing of those two
waves results in three waves. The third wave is a wave traveling
in the opposite direction to the other two. Thus the partial destructive
interference between the first two waves creates not only a forward wave
but a reverse wave. The question is: Is that reverse wave a "reflected"
wave since it was generated by wave interference. Are all waves traveling
in the direction opposite to the forward wave defined as reflected waves?
If so, Walt is correct. If not, Steve is correct.

>One reason the communications industry uses power to express signal >levels, the milliwatt is a power, is to avoid impedance related >arithmetic.

Hi Richard,

Such avoidance only occurs for the lineman in the telephone industry. Design and production engineering have much more to contend with. Even within the telephone industry, there are several power scales and ALL are specifically enumerated by nomenclature:
dBWre600
dBspl
dBrnC
dBm0

The purpose of such nomenclature is to allow for the impedance transformation from one system to another - not all sources/loads are 600 Ohms - not all sources/loads are electronic for that matter. All may be expressed in decibel power relationships - when qualified.

Academics and Amateurs do not often employ these full terms, industry knows better.

Let's take a ham transmitter case. A 100w IC-706 is outputting 70.7v at 1.414a into a 50 ohm dummy load. Now double the voltage ... whoops, the power control circuitry won't allow it. No problem, just reduce the dummy load to 25 ohms. Calculate the power. Hmmmmmm, what's wrong with this picture?

A very helpful ham emailed me with the fact that a ham transmitter is not a linear device as required by the superposition theorem. Steve's superposing of his two voltages requires an extra energy source. Is the ham transmitter capable of supplying that additional energy? The answer is no, so if Steve is even allowed to use the superposition theorem, he must locate that source of extra energy. No problem, we've already located it. The energy to support Steve's superposing waves comes from the cancellation of two other waves, the two waves involved in the interference pattern at the match point.

I'll be making a trip over to Texas A&M next week to research this subject. I studied the superposition theorem in depth at Texas A&M a number of years ago but it was from the perspective of a 60 Hz power engineer. Since frequency is scalable, the same principles apply. But it is interesting to note that, from a power engineer's standpoint, he only cares if the powers add up. That is not to say that he superposes powers but is to say that each EM wave has an intrinsic scalar energy that is what the power engineer is selling. No energy means no income for the power company.

Hey Tom, I don't add powers that way. That's Steve's technique.
He adds 75w plus 8.33w and gets 133.33w. I know better than to
add the voltages and currents and expect to obtain more energy
than exists.

Please show us how you can deliver 1v at 1a to each of two primaries
on a transformer and come up with 2v at 2a on the output. The power
companies would be very interested in that information.

Sasquatch,

I think that the SGC people did a bit of research on this with their QVC (Or whatever) multiband system. You might want to visit their site for the details but I think they found that a 10 mhz whip was the best compromise using their automatic tuner for an all band setup.

Richard, are you unfamiliar with the foundations of differential calculus?
Traveling an infinitesimal distance is perfectly consistent with the
math involved. Saying they only flow an infinitesimal distance is the
same thing as saying they are cancelled at a point because that distance
shrinks to zero in the limit. Look it up.

> Sorry Cecil, you not only said it, you underlined it and promoted it

Richard Clark wrote:
"The original topic concerned waves not sources."

That was long ago and the topic has evolved to include SWR which is of most interest as it affects the load presented to the source. This change from Zo as the load on the source only happens when a reflection returns.

Waves as a topic without tnteraction with their source may cause confusion because waves radiated in all directions can be focused in ever smaller beams. So effective radiated power in a small beam can almost be as large as you like.

Not so with a transmission line. It is restricted to only two directions of travel. You can only double the voltage into an open circuit and this is repeated every half wave back from the open. The only power to draw upon comes from the source via the line.

Best regards, Richard Harrison, KB5WZI

Who is it who has advocated the application of superposition
to power? Perhaps you are confusing the superposition theorem
with the principle of conservation of energy. Energy is a
scalar without phase so the superposition theorem doesn't apply.
It's unique property is that it can be added as a scalar, like
buckets of water, but it cannot be destroyed. That's an important
feature in keeping RF engineers from constructing a wave containing
more average energy than exists in the system.

Usually that is false. We have decibels referenced to a watt instead of a milliwatt, or to a volt in a particular system, or to a "C-weighting curve" for frequency response, or dBm0 which is the level at a specified point in the system, etc. My previous posting was correct.

You posted the impossible transformer configuration, not me.

> The unstated tenet
> (from you Cecil, and embraced by you as a common understanding -
> another failure of logic) is that the sources will not allow such
> combining on the terms offered. This is a failure of the model, not
> the theory.

Boy, are you mistaken. I never, never said that at all. I never said
that the sources will not allow such combining. I said that some of
the sources necessary to the combining were being ignored. Please
correct your beliefs about what I said.

> The original topic concerned waves, not sources. Cecil, you have
> argued a source limited argument against Steve's wave descriptions.

The source is there, Richard. Steve just won't admit it. The source
of energy that allows his voltages to add up to the proper value
is the energy involved in the wave cancellation.

> The same goes for your transformer argument that collapsed on just
> those same terms (and you failed even to notice how). Thus your model
> revealed a non-linearity to the issue at hand - it did not cope when
> the wave combined. Bluntly put, any appeal to the source for the
> action of a wave at a distance must implicate the entire model. Your
> arguments clearly lean heavily on the source offering some
> restriction, Steve's argument did not.

That's absolutely false, Richard. Both arguments assumed a 100w ham transmitter
driving a 50 ohm "load". The power is fixed, the voltage is fixed, the current
is fixed, and the load is fixed. Isn't that about as linear as we can get?

> Again, I would point out that Bart's thought example anticipates all
> these considerations and employs exactly the style of discussion you
> prefer. Bart's model completely divorces the sources from the
> mechanics of the waves. Bart's model is clearly superior.

If Bart's model completely divorces the sources from the mechanics of
the waves, then it risks violating the conservation of energy principle.
You can't get blood out of a turnip. If any source energy doesn't exist,
it doesn't exist. Even Bart cannot create energy out of the ether (or
is that aether?).

Richard, you and I don't communicate very well for some reason.
Sometimes, I read your relatively basic statements and have no
idea what you mean. To set the record straight about what I said
about Steve's treatment of power:

If there is not enough energy available to support superposition
of two waves, the resulting voltage will not be the sum of the
two voltages in the waves. We have seen that demonstrated with
the transformer examples.

"If" is the beginning of a conditional statement. If the "if"
portion of an if/then statement is false, the statement is true.
If there is enough energy available to support superposition,
the above statement is true. If there is not enough energy to
support superposition, the above statement is true. It is a
true statement, Richard. What I said was that *IF* Steve provides
ONLY 75 joules/sec + 8.33 joules/sec to his two superposing waves,
the voltages will not add up. We know the voltages do add up.
Therefore, he is providing more than 83.33 joules/sec to the
superposing process and just does not realize it. The extra 50
joules/sec is being supplied from the wave cancellation process.

Why complicate things? For starters, 97.15 deals only with amateur
installations, and vaguely at best, and doesn't say how near "near" is
which is what the poster was asking.

Here it is. 47 CFR 17.7 Apparently my link was only giving my cache
from the previous search.

Sec. 17.7 Antenna structures requiring notification to the FAA.

A notification to the Federal Aviation Administration is required,
except as set forth in Sec. 17.14, for any of the following construction
or alteration:
(a) Any construction or alteration of more than 60.96 meters (200
feet) in height above ground level at its site.
(b) Any construction or alteration of greater height than an
imaginary surface extending outward and upward at one of the following
slopes:
(1) 100 to 1 for a horizontal distance of 6.10 kilometers (20,000
feet) from the nearest point of the nearest runway of each airport
specified in paragraph (d) of this section with at least one runway more
than 0.98 kilometers (3,200 feet) in actual length, excluding heliports.
(2) 50 to 1 for a horizontal distance of 3.05 kilometers (10,000
feet) from the nearest point of the nearest runway of each airport
specified in paragraph (d) of this section with its longest runway no
more than 0.98 kilometers (3,200 feet) in actual length, excluding
heliports.
(3) 25 to 1 for a horizontal distance of 1.52 kilometers (5,000
feet) from the nearest point of the nearest landing and takeoff area of
each heliport specified in paragraph (d) of this section.
(c) When requested by the FAA, any construction or alteration that
would be in an instrument approach area (defined in the FAA standards

governing instrument approach procedures) and available information indicates it might exceed an obstruction standard of the FAA.
(d) Any construction or alteration on any of the following airports (including heliports):
(1) An airport that is available for public use and is listed in the Airport Directory of the current Airman's Information Manual or in either the Alaska or Pacific Airman's Guide and Chart Supplement.
(2) An airport under construction, that is the subject of a notice or proposal on file with the Federal Aviation

I don't want to beat this to death, but the information stated applies to any antennas including amateur radio antennas. The Part 97.15 200 foot rule simply doesn't say anything. Read 47CFR 17.7 and you'll see what I mean.

You're slippery as a greased eel, Cecil, but that remark was aimed
more at Richard Harrison than at you. I know yooouuu wouldn't
advocate superposition of power, oh no. You know full well that
you can't add powers the way you do tomatoes or radishes. How
silly of anyone to think you might think otherwise.

Hmmm...no luck up to this point. i can only get my antenna 10-12 feet off
the ground. Looks like I Could hear something but I'm not picking up
anything but static. Not even the SW stations. One problem...I've got a
100 ft of ladderline and it's only about 20 feet into my shack. What to do
with all the extra?

Why can't you add power (energy) like you do tomatoes
and radishes? Power engineers do it all the time. They
don't throw the switch until the voltages have the same
phase and eureka, they've just added two powers together.
But they don't add 75 watts and 8.33 watts and get 133.33
watts.

Cecil,

This brings up some additional questions.

When the power engineers add, say, 10 megawatts to an existing 10 megawatts what happens to all the extra power?

Am I required to turn on more lights in my house to absorb some of the extra power that is being forced into the line?

Unless there is a very unusual situation I would expect the power "forced" into the line under your scenario to be exactly equal to the demand.

It is likely that the sum of powers delivered by your generators is about the same after the switch is thrown as it was before. Paralleling the generators adds capacity, but it does not immediately change the actual delivered power unless the single generator was already overloaded. (But we know that overloads are *never* allowed in ham radio.)

72, (low on power)

That's true but the point was that the total power is equal to the
sum of the two powers delivered by the two generators just like the
total of the tomatoes is equal to the sum of the two shipments of
tomatoes from two farmers. Power is a scalar. Tomatoes is a scalar.
There is no way to add tomatoes out of phase. There is no way to
add power out of phase.

Tom, KA6RUH wrote:
"There is absolutely no mathematical justification for the concept of superposition of power whatsoever."

I don`t think you will find "superposition" in any of my postings.

As Cecil says: "Energy is a scalar without phase---."

The power factor of line impedance varies according to the standing wave situation. That`s because you are taking a summation.

When you examine the energy in one direction at a time, there is no opposite direction wave to consider and the power factor angle is zero, corresponding to a resistive impedance. That`s the basis of the Bird wattmeter. It works and only damn fools say it doesn`t.

Best regards, Richard Harrison, KB5WZI

I recall a discussion regarding problems caused by nickel plating on connectors, but the present discussion got me thinking about antenna materials.

Nickel is ferromagnetic, like iron, steel, and the stainless steel that most mobile whips are made from. So I'm curious as to whether the problem is due to having a thin coating of the material, whether the magnetic properties of nickel are particularly nonlinear compared to steel or other structural materials, or whether there might also be a problem with some steel antennas.

I've never had to deal with high power and/or low distortion RF systems, so don't have any first hand experience with this. The only trouble I've encountered with nickel plating is in its common use as a barrier metal between copper and gold plating on microstrip conductors. When the gold is too thin, allowing current to penetrate to the nickel at the frequencies of use, excessive loss occurs. Like other ferromagnetic materials, nickel is exceptionally lossy at high frequencies (and it's a frequency dependent loss) because the skin depth, being inversely proportional to the permeability, is very shallow. This isn't a problem with most steel antennas like whips and towers because the surface area is so big to begin with. But I don't think this has anything to do with the harmonic generation problem.

Gene Fuller wrote:
"When the power engineers add say 10 megawatts to an existing 10 megawatts what happens to all that extra power?"

As Gene knows, the consumption of the added 10 megawatts is not an event, it`s a growth of consumption which happens in the combined loads on the system. What the power engineers added was increased generating capacity.

With two machines in parallel, you can be sure the sum of the powers they generate equals the sum of the combined loads.

Power is not necessarily equally divided. It almost certainly isn`t immediately upon making the parallel connection. Excitation controls on each machine allow voltage adjustment to shift loads back and forth between machines as desired.

> off the ground.

Well, I suppose you oughta read the instructions. The Versa Tuner requires a jumper from the 'Wire' post to the Balanced Line post when you're using a balanced line. Now it's working like it should. Apparently, I need to get the antenna higher in the air but I'll have to make do for the time being. Also using a 10amp power supply so I can't use too much power. Got another power supply coming, probably next week.

Thanx for your input!

3094. Highest Gain on 10M Mobile Monopole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-16 00:55:01 UTC

Looking for highest gains practically measured on a 2 foot--or other very electrically small--10M monopole, vehicular mounted.

E-mail response works fine for me.

73,
Chip N1IR

You're absolutely right about the Bird wattmeter. It works.
It looks as if Cecil is going to start in on energy fields, now. This
should be interesting. Tomatoes and jalapenos... with cilantro.

If you're actually trying to say that you can add 3 dBm to 3 dBm and get 6 dBm, that's non-sensical. In non-log terms, that sum is equivalent to (2 mw) x (2 mw), or some quantity that is milliwatts squared. Absolutely no sense.

If you're trying to say that adding 3 dB and 3 dBm is a justification for adding powers, keep in mind that the sum is equivalent to (2) x (2 mw) or 4 mw. A simple multiplication.

Bill N3WK

3100. metallic IMD generators

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-16 02:53:01 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3d5c6d02_1@news1.prserv.net>
Source record: 136641

I have privately emailed a JPG of a page of the document to Roy. It is:
"Intermodulation in RF Coaxial Connectors" by M/A-Com, not Andrew.

Non-linear materials like Nickel anywhere RF current is flowing will cause intermod. The higher the current (connector center pins, half-wave element centers, and the like) the worse the problem. I suspect that a yagi with a nickel plated boom and only the element tips plated might be OK, but I wouldn't chance it. As far as stainless steel is concerned, I had the opportunity to compare some various metal rods on 150 MHz mobile antennas about 40 years ago, and the stainless were fractional dB poorer antennas than copper plated ones. Trouble was, no one could reliably keep the plating on over long term flexing. I suspect that mobiles may well be bad IMD sources, but the poor radiation characteristics and the mobility may limit the problem. Good area for some further investigation.

I won't comment on what you and Steve have been doing. Your simple
problems involve ideal theoretical transmitters, not real ones, so
that's not an issue. Sections of transmission lines are all linear, so
that's not an issue either.

> A source doesn't have to be linear under all conditions to satisfy

I'd agree, it's constant. Sounds like you talked yourself out of the emailer's concern. You might have to worry about source non-linearity if you were taking measurements at different frequencies or different drive levels.

> The energy needed for Steve's superposing is indeed supplied by the

Well, I hope you're not listening to their Morse code signals rattling through your fillings that says wave cancellation leads to jack-rabbit waves that jump in another direction because of conservation of energy.

Richard Clark wrote:
"Academics and amateurs do not often employ these full terms, industry knows better."

Well "debrinkos", etc are somewhat arcane. That`s dbrnc, or that`s db referenced to to noise at a level of -90 dbm with "C"-message level weighting. This is worked this way so the numbers will always be positive in value and relate to the transmission characteristics of certain telephone equipment.

Ever since Richard Clark questioned dBm0, etc, and I responded off the top off my head, I`ve been looking for the November 1961 edition of "The Lenkurt Demodulator" which was itself an update of a similar article from 1954 written by A.N. Seymour, the then Editor of the Demodulator. The Bell System adopted the 1954 article without change as an official "Bell System Practice". I found it and I was on target. The issue title is: "dba and Other Logarithmic Units". The intro says: In this article dba, dbrn, and vu are explained in detail. Shorter explanations of other units are also included.

I wish everyone could get reprints of all the Demodulators. They were the best little doses of technical information ever written. The quotations inclluded here are atypical as some wording is copied from official organizational definitions.

For dbm0: "The term dbm0 is a measure of power with reference to zero dbm at the reference transmission level point (RTLP). Power measured at any transmission level point can be expressed in dbm0 by correcting the power measured for the difference in level between the point of measurement and the Reference Transmission Level Point."

Best regards, Richard Harrison, KB5WZI

Hello All,

I am totally blind and despite being a ham for many years and possessing a pretty good knowledge of antennas, I am sometimes short of actual experience working with test equipment and the like. I am in the process of building a Battle Creek Trapper for which I want to wind coax traps for 80 and 40 meters. I do not have a grid dipper but do have access to the local dx club's MFJ 259B antenna analyzer. However, it does not have the add on to allow it to function as a grid dipper. Would some of you please suggest the best method for me to determine the exact resonant frequency of these traps using only the 259B? I have received some suggestions but would like to get a couple more before I tackle this project.

Thanks much for your suggestions and 73.

Bill Klocko wrote:
"If you`re trying to say that you can add 3 dbm to 3 dbm and get 6 dbm, that`s non-sensical."

3 dbm is twice the power of the 1 milliwatt reference, or 2 milliwatts. It`s a power, plain and simple. When 2 milliwatts is added to 2 milliwatts the only way I`ve succeeded in doing it, the sum is 4 milliwatts which is +6 dbm.

3 db is about a power ratio of (2).
6 db is about a power ratio of (4).
This works just fine and that`s all there is to it.

I`ve calculated the gains and losses for hundreds of microwave paths then gone out and measured a great number of them. You start with a transmitter power output of so many dbm, subtract waveguide and other losses, add the antenna gain, subtract the path loss in space, add another antenna gain, subtract another waveguide and misc. loss figures, and you have the received carrier power. The difference between the received carrier power and the receiver sensitivity is the fade margin. I`m not even going to check to see what I left out, but when I do the calculation carefully and test under the ordinary propagation conditions, I am usually on the nose plus or minus one db when the antennas are properly aligned. All you have to do is add and subtract db, know the microwave business and have system parts that meet their specifications. That is the normal, not the exception in my experience.

Best regards, Richard Harrison, KB5WZI

> Thanks for any insight!

Just get a single 10m hamstick. You can use it as is on 10m. Add longer
stinger whips to the top to work other bands. It depends on the design
of the hamstick, and how much whip they use for 10m, as to how much you
will need to tune 20m. Probably about 2 extra feet or so. If there is no
way to add whips to the top of the hamstick, you can use very small hose
clamps. Some sticks have a machined top to accept whips. Some don't.
Cheapest way to go 20-10 I know of. And it will work well if you mount
up on your hood. That would be better than the bumper. BTW, this would
cover the warc bands also if you had all the stingers. You will need a
matching device most likely for the lower of those bands. My present
mobile antenna works this way from 30-10 meters. I keep a collection of
stingers precut for each band. Also, the 10m hamstick on 20m, will
outperform most 20m hamsticks on 20m. It uses more whip and less coil.

Fred, you can't withdraw the suggestion or apologize without forming a
committee of at least five people to provide you wiith a feasibilty
study. If you think that the committee will form subcommittees, then
it best to have at least a dozen people involved. Give them at least
a year to report back; they may be eligible for a federal grant.

To accurately check resonant frequency of an antenna trap, place a
single-turn link of thin wire around the centre of the trap coil and take it
via an 8" pair of loosely-twisted thin wires to the antenna analyser.

Slowly vary frequency and search on the meter's Z-range for a VERY sharp
peak in impedance.

It's much better and satisfying than a dip oscillator.

I am about to install a Cushcraft R7 Vertical (a no-radial antenna). I intend to mount it on a mast, a metal pipe, driven about 4 to 5 feet into the ground. Would it be a good idea to do this or should I wall mount it? If ground mounting, what precautions should be taken for lightning? Is a seperate ground connection required in this case? What should be the minimum height of the antenna above ground? Any suggestions/ tips from your experience will be much appreciated. - 73's Raj

It may be difficult to wall-mount it because, if I remember correctly, there are several metal extensions at the base that stick out -- they look kind of like mini-radials. I know the R-7 works well when roof-mounted. Not sure how it would perform 4' above ground. It is a so-called 1/2-wave vertical; at least, electrically it is so.

As for grounding, I used to have an R-5, and there was no provision for grounding. I suspect the R-7 may be similarly configured. There's really no "ground-side" for this antenna, as there is for 1/4-wave verticals.

Good luck...

I guess lead, zinc, and mercury are not magnetically challenged and don`t distort a waveform. We solder and have mercury wetted relays and switches.

When I was a kid, we would amalgamate copper pennies with mercury to make them look more valuable. On gold it does the opposite.

I recently read a suggested method for joining copper tubes by cold soldering them with mercury. The tubing is cleaned as for soldering. The pieces to be joined are coated with mercury. Then, part (A) is inserted into part (B). After a few minutes the parts are immobile and after a few hours the parts are inseparable.

Has anyone made a cactus J-pole using mercury as the solder to join the pipes?

Best regards, Richard Harrison, KB5WZI

Which type of topographical (or is it topological?) projection of map is it than can be used to plot the actual direction to somewhere?

Or how would I calculate the direction given the map co-ordinates (degN/S, degE/W) of two places. Normal plane geometry Pythagoras wouldn't work, no?

Any internet web based tools for determining positional co-ordinates and direction would be useful as well.

It's for directional aerials.

A couple of quotes from Johnson: Section 6.3, page 150

"The power transmitted by a line can be expressed in a number of
equivalent ways. ...

P = E+^2/Z0 - E-^2/Z0

We can regard the first term in this expression as the power associated
with the forward-traveling wave, and the second term as the reflected
power."

Section 7.6, page 188

"A directional coupler, on the other hand, retains the advantages of
simplicity and small size, but, by responding only to the forward-
traveling wave, it gives an indication that is independent of its
position along the standing-wave pattern. The reflected power should,
of course, be subtracted from the incident power to obtain the correct
power absorbed by the load, but the error introduced by simply metering
the incident power does not increase very rapidly with the standing-
wave ratio."

And, finally, this goodie. Example 2: Lossless Line, page 137

"The over-all losses are small (al << 1), and so we can use the
principle of the conservation of power."

How's that for a reference?

>milliwatts which is +6 dbm.

Hi Richard,

I think that you are forgetting that "adding" two powers together is different from "increasing" a
power level by 3 db.
As you say, 1 milliwatt increased by 3 db is 2 milliwatts. But two 2 milliwatt sources added
together will not give you 4 milliwatts.

A good example is when combining two VHF transmitters into one antenna. Each transmitter
has an isolator followed by a cavity filter. The output of each cavity filter is connected to a
common "T" connector via a 1/4 wave cable. The third port on the "T" goes to the antenna. If a
watt meter is placed at the output of each transmitter and a third watt meter is placed after the T
we can see what happens. If each transmitter puts out around 120 watts and assume about 20
watts loss in the isloator and cavity, then about 100 watts from each transmitter will reach the
antenna watt meter.

Key each transmitter individually and you will see 100 watts from either on the antenna
watt meter. Key them both at the same time and you will see something greater than 200 watts.
What you see will depend on the phase relationship of the two waves at any given time. It may
show higher or lower the next time both are keyed up.

You must first add the voltages together before figuring power when two or more signals are
involved. You can not directly add two powers together. This is

important to do to make sure
that the peak voltage ratting of components are not exceeded.
Connectors cables etc.

100 watts into 50 ohms is 70.7 volts RMS That is approximately 100
volts peak which is also
200 watts peak with one transmitter. (E squared divided by R)

With 2 transmitters the voltage can be as much as 141.4 RMS or
approximately 200 volts peak
which is also 800 watts peak Depending on the phase relationship of
the two signals.

800 watts peak would be 400 watts average power if it were a steady
sine wave but when the
two signals are combined we do not get a pure sine wave out. It is a
complex wave.

Hi Richard,

It is only an accident that your response is correct to the literal
question. Bill made a poor choice in his example to illustrate a very
real possibility of error.

I will quote from an authority you will immediately accept without
qualification on this matter:
"Radio Propagation Handbook," Peter N. Saveskie, Appenidix 5,
DB POWER ADDITION:
Example 1: Add 6dBw and 2dBw (answer NOT 8dBW)....
Example 2: Add 10dBm and 10dBm (answer NOT 20dBm)....

And more examples following in the tedious thumping of nails into that
casket of adding power.

Just hang up 180 to 185 foot of wire. Raise the vertical part as high as ya
can. 50' seems a good spot. Tie the other end off ina tree somewhere down
the line.

Wrap 8 to 10 turns of coax in a 6 to 8" coil. Hook shield to ground rod and
a single 140 or so foot radial under the top wire if possible. And the
center of the coax coil to the radiating wire.

Adjuse length of "L" to resonance where you want it.

Stick a standard PI-Net tuner in line and work all bands with it.

Works for me.

>cheers, CAM, W5DXP

The Bird watt meter works but not always the way we might think it
does.
The forward and reflected power that it shows may not really be there!

Try this: put a watt meter between your transmitter and antenna tuner.
Put a second watt meter

between your tuner and a large resistor load, say 1000 ohms. Put a small amount of power out
of the transmitter and adjust the tuner for zero reflected power on the first watt meter. Adjust
the power so the first watt meter reads about 15 to 20 watts. The second watt meter, after the
tuner, will read around 100 watts. The reverse power on this meter will be 80 to 85 watts.
Subtracting the two gives the 15 to 20 watts delivered to the load.

But the forward reading of 100 watts can fool you into thinking that you have 100 watts going
forward with 85 watts reflected when in fact there is only 15 to 20 watts in the circuit as shown
by the first watt meter that is in a flat line!

The reason is because of the way the Bird watt meter measures power. (It really does not
measure power at all as others have shown.) It is only measuring the difference in two voltages
developed in the meters slug. The meter has no discrimination between voltages only current.
When the voltage is much higher than the current in the meter circuit it will dominate the
reading.

These are extreme conditions but is a good way to see what errors can be introduced.
